The NASA STI Program ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Program plays a key part in helping NASA maintain this important role.

The NASA STI Program provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Program is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Program's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Program, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Program.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Program, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON, and through DIALOG as the Aerospace Database.

The NASA STI Program gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Program, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **3121**

02 AERODYNAMICS **3122**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also 34 *Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **3135**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **3136**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **3145**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **3149**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **3150**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **3154**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **3155**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **3158**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **3159**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **3160**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **3160**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **3164**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **3164**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **3164**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance*, *39 Structural Mechanics*, and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION **3171**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **3171**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power*, *28 Propellants and Fuels*, *44 Energy Production and Conversion*, and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **3174**

24 COMPOSITE MATERIALS **3175**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **3186**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **3201**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **3211**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **3224**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power*, *20 Spacecraft Propulsion and Power*, and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **3227**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **3229**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **3240**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety*, and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **3261**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **3269**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **3286**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **3292**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 3297
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 3315
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 3316
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) 3324

43 EARTH RESOURCES AND REMOTE SENSING 3325
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 3336
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 3341
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 3354
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 3368
Includes weather forecasting and modification.

48 OCEANOGRAPHY 3376
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 3379

52 AEROSPACE MEDICINE 3387
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 3397
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 3399
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY ..... N.A.
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) ..... N.A.

60 COMPUTER OPERATIONS AND HARDWARE 3404
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 3406
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 3430
Includes computer networks and special application computer systems.

63 CYBERNETICS **3434**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **3451**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **3463**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **3466**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **3466**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) **3468**
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS **3477**
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS **3481**
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS **3494**
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS **3498**
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS **3503**
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS **3510**
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS **3522**
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) **3526**
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT **3526**
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE **3528**
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS **3536**
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY **3537**
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION **3537**
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) ..... **N.A.**

89 ASTRONOMY **3538**
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS **3542**
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION **3549**
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS **3550**
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION **3552**
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The application of advanced control concepts to air breathing engines may yield significant improvements in aircraft/engine performance and operability. Screening studies of advanced control concepts for air breathing engines were conducted by three major domestic aircraft engine manufacturers to determine the potential impact of concepts on turbine engine performance and operability. The purpose of the studies was to identify concepts which offered high potential yet may incur high research and development risk. A target suite of proposed advanced control concepts was formulated and evaluated in a two phase study to quantify each concept's impact on desired engine characteristics. To aid in the evaluation specific aircraft/engine combinations were considered: a Military High Performance Fighter mission, a High Speed Civil Transport mission, and a Civil Tiltrotor mission. Each of the advanced control concepts considered in the study are defined and described. The concept potential impact on engine performance was determined. Relevant figures of merit on which to evaluate the concepts are determined. Finally, the concepts are ranked with respect to the target aircraft/engine missions. A final report describing the screening studies was prepared by each engine manufacturer. Volume 1 of these reports describes the studies performed by Pratt & Whitney. Author (revised)

Scientific and Technical Aerospace Reports

A Monthly Publication of the National Aeronautics and Space Administration

01 AERONAUTICS (GENERAL)

N94-28537* National Aeronautics and Space Administration, Washington, DC.
AERONAUTICAL ENGINEERING: A CUMULATIVE INDEX TO A CONTINUING BIBLIOGRAPHY (SUPPLEMENT 300)
Feb. 1994 673 p
(NASA-SP-7037(300); NAS 1.21:7037(300)) Avail: CASI HC A99

This publication is a cumulative index to the abstracts contained in supplements 288 through 299 of Aeronautical Engineering: A Continuing Bibliography. The bibliographic series is compiled through the efforts of the Center for Aerospace Information of the National Aeronautics and Space Administration (NASA). Seven indexes are included: subject, personal author, corporate source, foreign technology, contract number, report number, and accession number. Author

N94-28666# Naval Aviation Logistics Center, Patuxent River, MD. Maintenance Office.
AIRCRAFT AGE IMPACTS ON MAINTENANCE REQUIREMENTS
John Johnson Sep. 1993 21 p
(AD-A275701) Avail: CASI HC A03/MF A01

Under the current defense environment, decreasing economic resources limit new aircraft acquisition programs. As a consequence the Services will be forced to operate aging aircraft without replacement for many critical missions. The impact of this average age increase upon future Operating and Support (O&S) costs must be assessed properly if the Department of Defense decision makers are to make properly informed downsizing decisions. The Naval Aviation Maintenance Office, Logistics Engineering Department, Resource Analysis Division, has developed methodology, techniques and procedures for evaluating potential relationships between the age of in service aircraft and their O&S costs using existing data bases. The incidence of verified material failures (VF) and the Direct Maintenance Manhours (DMH) expended to correct them are correlated to the aircraft's age during its in-service operational life and are potential indicators of increased O&S Costs. The Naval Aviation Logistics Data Analysis (NALDA) data bases for Navy and Marine Corp aircraft contain historical operations and maintenance data which can serve as age indicators. DTIC

N94-28732# Naval Aviation Logistics Center, Patuxent River, MD. Maintenance Office.
AIRCRAFT AGE IMPACT ON INDIVIDUAL OPERATING AND SUPPORT COST ELEMENTS
Laurence Stoll and Stan Davis Sep. 1993 40 p
(AD-A275739) Avail: CASI HC A03/MF A01

This study develops methodology, techniques and procedures for evaluation of age related cost trends associated with major categories of Operating and Support cost. Data sources including Naval Aviation Logistics Data Analysis (NALDA) history, Chief of Naval Operations Flying Hour Projection System Budget Analysis Reports, Visibility and Management of Operating and Support Cost Maintenance Subsystem and Total Support System reports, and Naval Depot Production Performance Reports (PPR's) were used to evaluate cost trends over the most recent ten years of cost data. Detailed data was collected on ten major Type Model Series aircraft including the P-3C, S-3A, F/A- 18A/B, F-14A, CH-53E, SH-60B, E-2C, SH-3H, CH-46E and A-6E. Evaluations of age related trends and recommendations for changes in current estimating processes when appropriate have been developed for the following cost categories; (1) O&I Level Consumables/Repair Parts (2) AVDLR's; (3) Aircraft Overhaul/Support; (4) Engine Overhaul/Support; (5) Petroleum, Oil, Lubricants (POL); (6) O and I level labor requirements. Results of this study clearly demonstrate age related trends of increasing costs linked to aircraft service life 'fleet age' for most of the categories under examination. DTIC

N94-28743# Air Force Inst. of Tech., Wright-Patterson AFB, OH. School of Logistics and Acquisition Management.
DEMONSTRATION OF IMPROVED SOFTWARE SUPPORT LABOR ESTIMATION FOR AIR FORCE OPERATIONAL FLIGHT PROGRAMS THROUGH FUNCTIONAL ORIENTATION M.S. Thesis
Ronald R. Warner, Jr. and Darrel L. Wright Dec. 1993 251 p
(AD-A275789; AFIT/GSS/LAS/93D-7) Avail: CASI HC A12/MF A03

This study demonstrated two approaches to improve current software support effort estimation models for aircraft software. Both approaches involved a functional orientation not used by existing models. The first approach demonstrated how to orient a model to reflect the block change cycle modification process and how to represent support effort changes over time in order to improve effort estimation accuracy. Current software models do not reflect the support environment or the temporal characteristics of aircraft software support. The second approach demonstrated how to calibrate a model by properly selecting source data in order to increase accuracy. Support calibration is not addressed by current models. A literature search affirmed the validity of both approaches and the methodology. In addition, a standard description of the block change cycle was developed and validated. A prototype estimation model was derived from the COCOMO model and included a unique support calibration. Data was obtained from Air Force Software Support Centers but was unusable, so data was generated from the prototype for the demonstration. A method that was developed to compare the prototype with current models demonstrated that the prototype is an acceptable model. DTIC

N94-29090 Aeronautical Research Labs., Melbourne (Australia).
FISHERMANS BEND: A CENTRE OF AUSTRALIAN AVIATION
J. L. Kepert Sep. 1993 75 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274981; ARL-GD-39; DODA-AR-008-377) Avail: CASI HC A04

Since 1919, Fishermens Bend, Victoria, has been a major center of Australian aviation. Many of Australia's great aviation achievements were born there. From its formation in 1939, the Aeronautical Research Laboratory, situated astride this activity at the Bend, has provided scientific and technical support to numerous aeronautical endeavors occurring in its surrounds. This report summarizes the many activities at the Bend from the first flight of an S11 Shorthorn from the Carey Airfield in 1919 to the production to the last indigenously built aircraft, the Nomad, in 1984. The aerodromes have long gone, the roar of aero-engines are contained within test cells, but the strong tradition of Australian aviation still lives on at the Bend today. DTIC

A TIME REASONING SYSTEM BASED ON THE EVENT CALCULUS FOR SCHEDULING IN AERONAUTIC MAINTENANCE Ph.D. Thesis - Toulouse Univ. [UN SYSTEME DE RAISONNEMENT TEMPOREL BASE SUR LE CALCUL D'EVENEMENTS POUR L'ORDONNANCEMENT EN MAINTENANCE AERONAUTIQUE]
Denys Bernard 1993 214 p In FRENCH
(Rept-932-710-101; ETN-94-95487) Avail: CASI HC A10/MF A03

Problems specific to the planning and scheduling of aircraft maintenance work sites are addressed. Methods presently employed and their associated problems are considered. The event calculus of Kowaslki and Sergot is introduced. Its adaptation to the domain of aircraft maintenance is considered, together with the associated inference rules. This permits an appropriate representation of the whole of the actions which are treated in a particular problem. A description of all the axioms characterizing the different types of situation for which a plan is to be prescribed is given. This presupposes that the scheduling takes out or prevents intervention of 'bugs' which could constrain the time organization of the actions. The sequencing processed by the computer architecture is considered. The organization of the system is explained. The last program tested is presented. ESA

N94-29842# Lawrence Livermore National Lab., CA.
DUAL-BAND INFRARED (DBIR) IMAGING INSPECTIONS OF BOEING 737 AND KC-135 AIRCRAFT PANELS
N. K. DelGrande, K. W. Dolan, P. F. Durbin, M. R. Gorvad, and A. B. Shapiro 27 Aug. 1993 55 p
(Contract W-7405-eng-48)
(DE94-005700; UCRL-CR-115237) Avail: CASI HC A04/MF A01

We apply dual-band infrared (DBIR) imaging as a dynamic thermal tomography tool for wide area inspection of a Boeing 737 aircraft and several Boeing KC-135 aircraft panels. Our analyses are discussed in this report. After flash-heating the aircraft skin, we record synchronized DBIR images every 40 ms, from onset to 8 seconds after the heat flash. We analyze selective DBIR image ratios which enhance surface temperature contrast and remove surface-emissivity clutter (from dirt, dents, tape, markings, ink, sealants, uneven paint, paint stripper, exposed metal, and roughness variations). The Boeing 737 and KC-135 aircraft fuselage panels have varying percent thickness losses from corrosion. We established the correlation of percent thickness loss with surface temperature rise (above ambient) for a partially corroded F-18 wing box structure and several aluminum reference panels. Based on this correlation, lap splice temperatures rise 1 C per 24 +/- 5 % material loss at 0.4 s after the heat flash. We show tables, charts and temperature maps of typical lap splice material losses for the riveted (and bonded) Boeing 737 and the riveted (but unbonded) Boeing KC-135. We map the fuselage composite thermal inertia, based on the (inverse) slope of the surface temperature versus inverse square root of time. Composite thermal inertia maps characterize shallow skin defects within the lap splice at early times (less than 0.3 s) and deeper skin defects within the lap splice at late times (greater than 0.4 s). Late time composite thermal inertia maps depict where corrosion-related thickness losses occur. Lap splice sites on a typical Boeing KC-135 panel with low composite thermal inertia values had high skin-thickness losses from corrosion. DOE

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

STEADY PRESSURE MEASUREMENTS ON AN AEROELASTIC RESEARCH WING (ARW-2)
Maynard C. Sandford, David A. Seidel, and Clinton V. Eckstrom Feb. 1994 537 p
(RTOP 505-63-50-15)
(NASA-TM-109046; NAS 1.15:109046) Avail: CASI HC A23/MF A04

Transonic steady and unsteady pressure tests have been conducted in the Langley transonic dynamics tunnel on a large elastic wing known as the DAST ARW-2. The wing has a supercritical airfoil, an aspect ratio of 10.3, a leading-edge sweep back angle of 28.8 degrees, and two inboard and one outboard trailing-edge control surfaces. Only the outboard control surface was deflected to generate steady and unsteady flow over the wing during this study. Only the steady surface pressure, control-surface hinge moment, wing-tip deflection, and wing-root bending moment measurements are presented. The results from this elastic wing test are in tabulated form to assist in calibrating advanced computational fluid dynamics (CFD) algorithms. Author (revised)

N94-28674# Naval Postgraduate School, Monterey, CA.
AERODYNAMIC DESIGN USING PARALLEL PROCESSORS Ph.D. Thesis
Stephen C. Brawley Sep. 1993 152 p
(AD-A275470) Avail: CASI HC A08/MF A02

An airfoil design technique has been developed which decreases the computational processing time by more than an order of magnitude when optimizing aerodynamic performance. The practicality of airfoil design using parallel processors and Navier-Stokes flow solvers has been demonstrated. Typically, an airfoil is designed to meet certain criteria based upon its aerodynamic performance at set flight conditions. If an optimization technique is used for airfoil design, the shape of the airfoil is varied, and the aerodynamic performance of numerous airfoil geometries are evaluated using computational fluid dynamics. Multiple aerodynamic performance evaluations require the vast majority of computational processing time used in airfoil design optimization. DTIC

An experimental study involving interaction between streamwise wing-tip vortices and a two-dimensional lifting surface in a supersonic stream was conducted. The experiments were designed to simulate interaction of supersonic vortices with aerodynamic surfaces of high-speed aircraft and missiles. The experimental scheme involves positioning an instrumented two-dimensional wedge downstream of a semi-span wing so that the trailing tip-vortex from the wing interacts with the aerodynamic surface. Experimental results indicate that the interaction strongly depends on the vortex strength and vortex proximity to the wedge leading edge. In their most organized form, distortion of streamwise vortices upon interacting with the wedge was found to result in formation of symmetric detached shock fronts far upstream of the wedge leading edge followed by an apparent slip surface separating a subsonic region from a supersonic zone. Interaction of vortices with oblique shock wave over the wedge section indicates that interaction of a relatively weak vortex with a moderate strength oblique shock does not lead to significant changes in the vortex structure. On the other hand, interaction of a moderate strength vortex with a strong oblique shock results in the formation of a detached shock wave upstream of the oblique shock front. DTIC

Mathematics software is of growing importance for computer simulation in industrial computer aided engineering. To be applicable in industry, the mathematics software and supporting software must be structured in such a way that functions and performance can be maintained easily. In the present paper, a method is described for development of mathematics software in such a way that this requirement can be met.

The validity of the Variable Soft Sphere (VSS) molecular model, which is consistent with both the viscosity and diffusion coefficients of any intermolecular potential, is investigated by the Monte Carlo simulation of the shock wave structure in binary gas mixtures of Maxwell molecules. Calculations are made by the null-collision direct-simulation Monte Carlo method. The VSS model yields the same shock wave structures as Maxwell molecules even when the Variable Hard Sphere (VHS) molecular model reveals a different structure. The computation time and simplicity of the VSS model are confirmed to be almost the same as those of the VHS model. The VSS model is, therefore, preferable to the VHS model in practical use. Using the reliable values of the VSS parameters, the shock wave structure in He and Xe gas mixtures is investigated to compare with the measured density profiles. The density gradient and separation distance are in reasonable agreement with the experimental results.

Numerical simulations on unsteady shock reflections by a ramp have been conducted in order to investigate unsteady aerodynamic heating due to shock reflection processes at higher incident shock Mach number. The two-dimensional Navier-Stokes equations with thin layer approximation are solved numerically by a TVD (Total Variation Diminishing) scheme. The effect of mesh refinement to the calculated results is investigated carefully. The results show the smaller mesh size is necessary for calculating precise aerodynamic heating loads and capturing the fine structure of the shock reflection patterns. Author (NASDA)

Modern shock capturing schemes, i.e., solution adaptive interpolatory schemes, supply beautiful solutions, so they are used generally even in the industrial world. There is a problem in shock capturing schemes, however, when there are plural shocks within the grid points constructing a numerical flux. In order to stabilize a numerical solution in such a scheme, the accuracy must be degenerated. Such a situation can be often seen in two dimensional flow field, and steady Mach reflection is a typical example of the plural shock flow. An analytical solution of the steady Mach reflection was shown, and an investigation of shock capturing scheme performance by comparing it with present analysis was proposed. In this report, a newly developed scheme was also used to investigate the characteristics of the shock capturing schemes, and the performances of TVD (Total

Variation Diminishing) scheme and of the new scheme were compared. Carbuncle phenomena and entropy layer on the wall were also discussed.

The purpose of the present paper is to perform direct numerical simulations of the time-developing subsonic and supersonic mixing layers. In order to simulate unsteady shock-vortex interactions accurately, a fourth-order accurate shock capturing scheme is used. This scheme is based on the third-order accurate upwind finite-difference scheme and the accuracy can be extended to fourth(fifth)-order by adopting additional compact terms into the schemes. The resolution is higher than the existing scheme and the algorithm is simpler than the ENO (Essentially Non-Oscillatory) scheme. Finally, some numerical results of subsonic and supersonic mixing layers are shown and the reliability is discussed in comparison with the ordinary numerical scheme. Author (NASDA)

The underlying idea of the widely used and accepted multiblock approach for flow analysis is to subdivide a geometrical complex flow domain region into several smaller, more manageable regions, referred to as blocks. Typically there are several individual blocks in a given flow domain, each block having three computational coordinates. In the present approach the grid generation process is divided into two sub-processes: (1) block decomposition, i.e., the creation of blocked flow domains; and (2) grid generation, i.e., the computation of structured grids in the blocks. The ENGRID code is a general purpose multi-block grid generation code for the computation of Euler or Navier-Stokes types of grids in flow domains which are already subdivided into blocks. The two required input files for ENGRID are a topology and a geometry file. The topology file defines the topology of a multi-block flow domain. The topology of a blocked flow domain describes how the blocks are connected to each other. The geometry file contains the geometrical information of a multi-block flow domain. The file contains the geometrical definition of all vertices, all non-default elementary edges, and all non-default elementary faces. Author (NASDA)

Recent progress in the performance of helicopters has been so remarkable that maximum speeds of over 200 knot are not uncommon among experimental helicopters. Such high performance owes much to the progress in rotor aerodynamics, especially the development of advanced airfoils. Additionally, the recent progress in Computational Fluid Dynamics (CFD) and supercomputers has been quite remarkable. These improvements make it possible to accurately predict airfoil performance up to and beyond maximum lift, where viscous and vortical effects prevail. A practical design target was identified. The target was to obtain airfoil shapes with comparable performance to that of Boeing Helicopter's third-generation airfoils, VR-12 through VR-15. Prior to the design, a parametric study on leading edge thickness and camber was carried out. The study depended upon the fact that the maximum lift of airfoils is related to leading edge shape. An optimal combination of leading edge thickness and camber was decided during the parametric study. Then, the shape, especially around the leading edge, was successively refined by relaxing the leading edge pressure peak to realize much higher maximum lift without spoiling other performance. Finally, off-design and overall characteristics were verified up to transonic Mach numbers. The airfoil U896H thus designed, has a thickness over chord ratio of 0.10 and has symmetric section shape except for the optimized cambar around the leading edge. Wind tunnel results of the airfoil showed high maximum lift and high drag divergence Mach number as expected and enough to be among third-generation airfoils. Author (NASDA)

Numerical analysis of supersonic transport wings was carried out. The drag reduction obtained by using the warped wing design technique is from 0.0006 to 0.0010 in supersonic cruise condition. It is also clarified that the drag reduction by use of Euler analysis is less than that by the linear method, because the flow mechanism in supersonic region is essentially non-linear. Finally it is shown that the cranked arrow wing-body configuration has the best lift to drag ratio in supersonic cruise condition in comparison with delta or ogee wing-body configuration.

Airframe-integrated scramjet engines are now proposed as one of the most promising propulsion systems for hypersonic transports and transatmospheric vehicles for single-stage-to-orbit. Such engines are composed of several modules, each of which consists of an air-intake, a combustion chamber, and a nozzle, and these modules are attached side by side to the bottom surface of the fuselage of a vehicle. In such a configuration, it is considered that when disturbances cause one of the modules to be unstarted, such influences propagate to the adjoining modules through the intake and/or the nozzle, and that the normal operation of the propulsion system should be destroyed. In this study, such interactions between modules of the airframe-integrated scramjet engines are investigated numerically. Shock waves generated by thermal choke in the heating region of the module are used to trigger unstart. The flow field, including the yaw cross section of the modules, is approximated. An inviscid compressible flow is assumed, so Euler equations with heating terms are used as the governing equations. The explicit symmetric TVD (Total Variation Diminishing) scheme is used. From the two-dimensional calculations, the following conclusions are obtained: (1) when thermal choke occurs in one module of a scramjet engine, its influence reaches the adjoining modules through shock wave propagation and they become unstarted; and (2) the transient process from the started condition to unstarted is completed in about 30 msec, and the unstarted modules generate not thrust but drag.

Airframe-engine integration is one of the most important problems in the area of supersonic inlet technologies. In the present paper the flow around an airframe-engine integration model is numerically simulated. Because of the geometrical complexity, the overlaid composite grid approach, based on the Fortified Solution Algorithm (FSA) concept, is used for the discretization strategy. In the present computation, the composite grid consists of four component grids. The primary grid is constructed with respect to the airframe, and the subsidiary grids are generated about the nacelle, duct, and diverter. The minor grids are used to resolve the features of the engine geometry and are overlaid on the main grid. The inviscid flow field is solved for this configuration at a Mach number of 2.75 and zero deg angle of attack. Although the overall flow features are successfully simulated by this preliminary computation, further improvement of the solution quality by grid enrichment and the discussion about the flow field are left as future work.

Numerical solutions of 3-D Euler equations are obtained for supersonic flows in order to investigate the sonic boom pressure signatures in the near field. The models used in the calculations are a body of revolution and two wing-body configurations. The results for the body of revolution indicate good agreement with the experimental data. A solution-adaptive-grid method which uses tension and torsion spring analogies is applied. The results show that this method improves the accuracy of solutions, and that sharper pressure signatures can be calculated than those in the initial grid.

Numerical analysis of chemically and thermally non-equilibrium hypersonic flow around a sphere are carried out. Two-dimensional and axisymmetric full Navier-Stokes equations which have chemical and thermal non-equilibrium effects are considered by using Park's two-temperature model and the Landau-Teller vibrational relaxation model. An efficient numerical algorithm is constructed which consists of the combination of LU-SGS (Lower Upper-Symmetric Gauss-Seidel) schemes and the implicit diagonal method for a source Jacobian matrix for the time integration of an implicit finite difference method and MUSCL-type (Monotonic Upstream Centered Schemes for Conservation Laws) TVD (Total Variation Diminishing) scheme based on Roe-type flux splitting for convective terms. Shock location of both numerical results and experimental data are compared and good agreement is obtained in the wide range of Mach numbers up to M(sub infinity) = 16. Shock capturing capability is good enough to describe very strong discontinuity with no more than three grid points. Author (NASDA)

In the present study, periodic flows are simulated around NACA 0012 airfoil at high angle of attack to validate the unsteady Navier-Stokes code. Thin-layer approximated unsteady Navier-Stokes equations are integrated in a time-dependent manner with Baldwin-Lomax turbulence model. With Mach number, 0.3 and Reynolds number, 6 x 10(exp 6), characteristics of lift, drag and moment coefficients are investigated at a variety of angles of attack. The simulated flows are compared qualitatively with experimental results obtained by flow visualization conducted in a low-speed tunnel at higher angles of attack than that at which 'stall' occurs. The similar periodicity of the flows is found in the experimental result. Author (NASDA)

This paper proposes a new formulation for the incompressible N-S (Navier-Stokes) equations by introducing a new variable q, the rotation of which represents the convective and pressure gradient terms of the momentum equations. The derived governing equations consist of the linear dynamic equations and the Poisson equation for the new variable q with the nonlinear source. These equations automatically satisfy the divergence free condition. The boundary condition for the new variable q is the Dirichlet type, the Poisson equation can be quickly solved by the conventional point relaxation method. Furthermore, a new method to economically obtain the corresponding pressure field is also proposed. Applications to a driven cavity flow and the flow around a circular cylinder show excellent performances of the new method. Author (NASDA)

Numerical simulations of 3-D shear flows are carried by solving the pseudo-compressibility equations for incompressible fluid proposed by Chakravarthy. Governing equations are integrated explicitly in time by a third order upwind finite volume scheme. A steady 3-D duct flow over a backward-facing step, and 3-D spatially developing incompressible mixing layer are solved, and it is shown the results of numerical simulation using the present methods is reasonable. Investigated are characteristics of the approximate Riemann solvers, which are used as a building block for construction of modern shock-capturing schemes. Then a new approximate Riemann solver is proposed, which is a result of an improvement of HLLEM (Harten Lax van Leer Einfeldt Modified) scheme, satisfying the positivity condition and entropy one. Also its generalization for nonequilibrium flows such as high-temperature gas is described. Some numerical results are presented as well.

ANALYSIS OF 3-D ACOUSTIC PROBLEMS USING BOUNDARY ELEMENT METHOD [KYOKAI YOSOHO NIYORU SANJIGEN ONKYO KAISEKI] **c71**
Mitsunori Yanagizawa *In* NAL, Proceedings of the 10th NAL Symposium on Aircraft Computational Aerodynamics Dec. 1992 p 153-156 In JAPANESE (For primary document see N94-28946 08-02)
Avail: CASI HC A01/MF A03

This paper is concerned with the development of a numerical method for the prediction of the characteristics of a sound field using boundary element analysis. An acoustics field in inner or exterior problems of harmonic vibration is governed by the Helmholtz equation. It can be solved by a boundary condition and an initial condition being given. Unknown values of acoustic pressure on the boundary are analyzed by the boundary element method using boundary conditions. After this procedure, the values of acoustic pressure at the inside point can be calculated from those of the boundary. This procedure allowed substantial saving of memory. Analysis with a personal computer became possible. According to these results, it was shown that the calculations can be carried out sufficiently with a small computer in spite of the small memory capacity. Small computers, which are very popular, will become an effective tool in numerical simulation with boundary element method. Author (NASDA)

The effects of the injection methods on mixing of hydrogen in the free stream are investigated. The numerical simulations are performed by solving the full two-dimensional Navier-Stokes equations using the explicit symmetric total variation diminishing (TVD) scheme. As for the injection methods, single injection, tandem injection, and parallel injection are examined. The injected hydrogen mass flow is constant in all cases. Injection methods are evaluated by the correlation between the mixing efficiency and the mass flow averaged total pressure loss at the outlet boundary of the computational region. First, the injection angle is varied in case of single injection. The results show that the more forward the injection angle is leaned, the more deeply hydrogen penetrates into the free stream. Second case is tandem injection, and the distance between or mass flow ratio of two injections is varied. The results show that the upstream injection blocks the main stream, so the barrel shock of the downstream injection becomes larger and dominant in mixing in tandem injection. Last is parallel injection, and the distance from the wall to the injection is varied. The results show that parallel injected hydrogen can be mixed in the free stream in spite of the fact that it has no momentum perpendicular to the free stream. The correlations between the mixing efficiency and the total pressure loss in all cases show that the mixing efficiency in the parallel injection is two times as much as in other methods of injection. A transonic flowfield around rotor blades of a highly loaded single stage axial compressor was numerically analyzed by a three dimensional compressible Navier-Stokes equation code using Chakravarthy and Osher type total variation diminishing (TVD) scheme. A stage analysis which calculates both flowfields around inlet guide vane (IGV) and rotor blades simultaneously was carried out. Comparing with design values and experimental data, computed results show slight difference quantitatively. But the numerical calculation simulates well the pressure rise characteristics of the compressor and its flow pattern including strong shock surface. Author (NASDA)

This paper presents an application of the three dimensional Navier-Stokes computations in designing a turbine vane cascade. The accurate prediction of the cascade flow characteristics such as total pressure loss and outlet flow angle is important for aerodynamic engineers to evaluate the performance of airfoil contour shapes. Curvilinear leaned and swept stator vanes, adopted to suppress the secondary flow and reduce the losses, are studied in detail. The advanced design based on the three dimensional Navier-Stokes computations succeeded in reducing the losses, showing the capability of the code as a design tool. Author (NASDA)

A new approach to compute external viscous flows around three dimensional configurations is proposed. A prismatic grid is used where the three dimensional surface is covered by triangles similar to the unstructured grid. The direction away from the body surface is structured so as to achieve efficient and accurate computations for high Reynolds number viscous flows. The prismatic grid is generated by a newly developed marching-type procedure in which grid spacings are controlled by a variational method. The capability of the method is demonstrated by applying it to a viscous flow computation around a complete aircraft configuration. Author (NASDA)

New methods for adaptive grid generation through optimal regulator of digital control are presented. The performance index of linear optimal regulator problem has a strong relation to the characteristics of adaptive

grid generation. Paying attention to this point, one and two dimensional Poisson equations are transformed into the state-space form. The numerical examples of NACA-0012 airfoil flow field and supersonic flow around corners show strong clustering of grid lines at shock waves through these two kinds of adaptation. Author (NASDA)

Several approaches based on the polynomial which approximates the local solutions to the governing equations have been proposed. The polynomial is piecewisely determined by interpolating the physical quantities on a point aimed at solving the equations and an adequate number of surrounding points. The derivatives at the point are evaluated by using this interpolated polynomial. Most of the conventional methods can be classified by the kinds of polynomial and the use of the interpolation. It may be considered that this basic concept is useful for constructing a method in which the results are independent of grid systems. Also, it seems that to find an appropriate interpolation may contribute to constructing a multidimensional upwind scheme. Author (NASDA)

Avail: CASI HC A02/MF A03

An implicit upwind relaxation scheme has been developed for computing compressible inviscid flows using a composite zonal grid system or an unstructured grid. The three dimensional Euler equations are discretized spatially by a cell-centered finite volume formulation, in which the inviscid fluxes are evaluated using a highly accurate upwind scheme based on the Roe's approximate Riemann solver. A new time-linearization of the inviscid fluxes evaluated by the Roe's approximate Riemann solver is presented. No approximate factorization is introduced, and unfactored implicit equations are solved by a pointwise relaxation method. Numerical examples are presented for the inviscid flows through a transonic duct and a diagonal flow impeller. The present scheme was found to be stable at CFL (Courant Friedrichs Lewy) numbers of over 10(exp 5). Author (NASDA)

Numerical analysis was conducted for the laminar flow and heat transfer in a square sectioned U-bend which rotates at constant angular velocity about an axis parallel to a center of the bend curvature. In a rotating U-bend, secondary flow develops under the effects of Coriolis force and centripetal force which affects its friction and heat transfer. The flow was characterized by five parameters: K(sub LC), Ro, lambda, lambda/Ro, and Pr. The calculations were conducted with various combinations of these parameters. Author (NASDA)

The secondary flow due to Coriolis force takes place when viscous fluid flows through a straight pipe rotating about an axis perpendicular to the pipe axis. This is analogous to the secondary flow due to centrifugal force in the flow through a stationary curved pipe. The quantitative similarities between the two flows are demonstrated for turbulent flow by the similarity arguments and computational study using kappa-epsilon turbulence model. It is demonstrated that the mutual similarity between two flows is established for friction factors and flow patterns. Author (NASDA)

The assumed highly parallel vector computer with hierarchical memory that consists of many vector computers with local memory and one common memory is the main theme. To speed up parallel processing of CFD (Computational Fluid Dynamics) programs on that parallel computer, it needs parallelization techniques such as enlarging parallel portion, equal work load, enlarging task granularity and minimizing volume of data access between local memory and common memory. In this paper high efficiency of parallel processing of that parallel computer obtained by applying parallelization techniques to a CFD program is described.

This report summarizes the results of the research in two parts. Part I describes the development and application of a free-wake Euler and Navier-Stokes computational fluid dynamics method, called 'TURNS', for helicopter applications. This finite-difference, implicit, upwind numerical method uses structured grids, and has been used for calculating the viscous, three-dimensional flow-fields of rotors in hover, forward flight, blade-vortex interactions, and high speed impulsive noise. The good agreement of numerical results with experiments for surface pressures, wake trajectory, thrust, power, Figure of Merit, and acoustic wave forms indicate the accuracy and suitability of the numerical method. It is demonstrated that both aerodynamics and acoustics information can be obtained in a single solution of the governing equations. In Part II, the unsteady flowfield results of a two-dimensional oscillating wing are presented for five widely used turbulence models and compared with experiments. The accuracy and suitability of turbulence models for unsteady separated flow are discussed. DTIC

An experimental study of the tip vortex behind a NACA 0015 rectangular wing of aspect ratio 4 was carried out to understand the structure and evolution of the vortex in the near-wake region. The results of these experimental studies are presented in this report. These measurements were made nonintrusively using three-component laser-Doppler velocimetry (LDV). The experiments were carried out at a Reynolds number of about 180,000 in a low-speed wind tunnel. Two cases were studied, namely: (1) stationary wing, and (2) wing oscillating in pitch sinusoidally about its quarter-chord axis. The flow properties measured were the three components of the instantaneous velocity. These data were processed to obtain time-mean and phase-locked flow properties such as velocity, vorticity and turbulence. The data were obtained at several locations at 0.15 - 3.0 chord lengths downstream from the trailing edge. The typical distributions of mean velocity, vorticity, circulation and turbulent intensity in the near wake are presented and discussed for the stationary wing. In the case of the oscillating wing, the phase-locked velocity, vorticity and turbulence data

show details of the evolution of the unsteady tip vortex downstream from the trailing edge. The results also show that the flow is strongly non-quasi-steady at the oscillation frequency studied. The results are fully archived on tape and are available to any interested reader. These can be used as database in the development of wake models for the finite wing, and in studies of three-dimensional wing aerodynamics DTIC

LOW-SPEED LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A FLAT-PLATE PLANFORM MODEL OF AN ADVANCED FIGHTER CONFIGURATION

Brian E. McGrath (Lockheed Engineering and Sciences Co., Hampton, VA.), Dan H. Neuhart (Lockheed Engineering and Sciences Co., Hampton, VA.), Gregory M. Gatlin, and Pat ONeil Mar. 1994 36 p Original contains color illustrations

(RTOP 505-68-70-05)

(NASA-TM-109045; NAS 1.15:109045) Avail: CASI HC A03/MF A01; 8 functional color pages

A flat-plate wind tunnel model of an advanced fighter configuration was tested in the NASA LaRC Subsonic Basic Research Tunnel and the 16- by 24-inch Water Tunnel. The test objectives were to obtain and evaluate the low-speed longitudinal aerodynamic characteristics of a candidate configuration for the integration of several new innovative wing designs. The flat plate test allowed for the initial evaluation of the candidate planform and was designated as the baseline planform for the innovative wing design study. Low-speed longitudinal aerodynamic data were obtained over a range of freestream dynamic pressures from 7.5 psf to 30 psf (M = 0.07 to M = 0.14) and angles-of-attack from 0 to 40 deg. The aerodynamic data are presented in coefficient form for the lift, induced drag, and pitching moment. Flow-visualization results obtained were photographs of the flow pattern over the flat plate model in the water tunnel for angles-of-attack from 10 to 40 deg. The force and moment coefficients and the flow-visualization photographs showed the linear and nonlinear aerodynamic characteristics due to attached flow and vortical flow over the flat plate model. Comparison between experiment and linear theory showed good agreement for the lift and induced drag; however, the agreement was poor for the pitching moment. Author (revised)

AN EXPERIMENTAL AND THEORETICAL STUDY OF THE AERODYNAMIC CHARACTERISTICS OF SOME GENERIC MISSILE CONCEPTS AT MACH NUMBERS FROM 2 TO 6.8

M. Leroy Spearman and Dorothy O. Braswell Apr. 1994 31 p

(RTOP 505-69-20-01)

(NASA-TM-109110; NAS 1.15:109110) Avail: CASI HC A03/MF A01

A study has been made of the experimental and theoretical aerodynamic characteristics for some generic high-speed missile concepts at Mach numbers from 2 to 6.8. The basic body for this study had a length-to-diameter ratio of 10 with the forward half being a modified blunted ogive and the rear half being a cylinder. Modifications made to the basic body included the addition of an after body flare, the addition of highly swept cruciform wings and the addition of highly swept aft tails. The effects of some controls were also investigated with all-moving wing controls on the flared body and trailing-edge flap controls on the winged body. The results indicated that the addition of a flare, wings, or tails to the basic body all provided static longitudinal stability with varying amounts of increased axial force. The control arrangements were effective in producing increments of normal-force and pitching-moment at the lower Mach numbers. At the highest Mach number, the flap control on the winged body was ineffective in producing normal-force or pitching-moment but the all-moving wing control on the flared body, while losing pitch effectiveness, still provided normal-force increments. Calculated results obtained through the use of hypersonic impact theory were in generally good agreement with experiment at the higher Mach numbers but were not accurate at the lower Mach numbers.

EXPERIMENTAL STUDIES OF TRANSONIC FLOW FIELD NEAR A LONGITUDINALLY SLOTTED WIND TUNNEL WALL Ph.D. Thesis - George Washington Univ., 1988

Joel L. Everhart and Percy J. Bobbitt Apr. 1994 73 p

(RTOP 506-40-41-01)

(NASA-TP-3392; L-16423; NAS 1.60:3392) Avail: CASI HC A04/MF A01

The results of detailed parametric experiments are presented for the near-wall flow field of a longitudinally slotted transonic wind tunnel. Existing data are reevaluated and new data obtained in the Langley 6- by 19-inch Transonic Wind Tunnel are presented and analyzed. In the experiments, researchers systematically investigate many pertinent wall-geometry variables such as the wall openness and the number of slots along with the free stream Mach number and model angle of attack. Flow field surveys on the plane passing through the centerline of the slot were conducted and are presented. The effects of viscosity on the slot flow are considered in the analysis. The present experiments, combined with those of previous investigations, give a more complete physical characterization of the flow near and through the slotted wall of a transonic wind tunnel.

AN EXPERIMENTAL STUDY OF THE FLOWFIELD ON A SEMISPAN RECTANGULAR WING WITH A SIMULATED GLAZE ICE ACCRETION Ph.D. Thesis

Abdollah Khodadoust 1993 252 p

Avail: Univ. Microfilms Order No. DA9314893

The effect of a simulated glaze ice accretion on the flowfield of a semispan, reflection-plane, rectangular wing at Re = 1.5 million and M = 0.12 was investigated. A laser Doppler velocimeter was used to map the flowfield on the upper surface of the model in both the clean and iced configurations at alpha = 0, 4, and 8 degrees angle of attack. At low angles of attack, the massive separation bubble aft of the leading edge ice horn behaved in a manner similar to laminar separation bubbles. At alpha = 0 and 4 deg, the locations of transition and reattachment, as deduced from momentum thickness distributions, were in good agreement with transition and reattachment locations in laminar separation bubbles. These values at y/b = 0.470, the centerline measurement location, matched well with data obtained on a similar but two dimensional model. The measured velocity profiles on the iced wing compared reasonably with the predicted profiles from Navier-Stokes computations. The iced-induced separation bubble also had features similar to the recirculating region aft of rearward-facing steps. At alpha = 0 and 4 deg, reverse flow magnitudes and turbulence intensity levels were typical of those found in the recirculating region aft of rearward-facing steps. The calculated separation streamline aft of the ice horn at alpha = 4 deg, y/b = 0.470, coincided with the locus of the maximum Reynolds normal stress. The maximum Reynolds normal stress peaked at two locations along the separation streamline. The location of the first peak-value coincided with the transition location, as deduced from the momentum thickness distributions. The location of the second peak was just upstream of reattachment, in good agreement with measurements of flows over similar obstacles. The intermittency factor in the vicinity of reattachment at alpha = 4 deg, y/b = 0.470, revealed the time-dependent nature of the reattachment process. The size and extent of the separation bubble were a function of angle of attack and spanwise location. Three dimensional effects were strongest at alpha = 8 deg. The calculated separation and stagnation streamlines varied little with spanwise location at alpha = 0 deg. The calculated separation streamlines at alpha = 4 deg revealed that the bubble was largest near the centerline measurement plane, whereas the tip-induced vortex flow and the model root-tunnel wall boundary layer interaction reduced the size of the bubble. These effects were most dramatic at alpha = 8 deg. Dissert. Abstr.

NUMERICAL STUDY OF THE TRAILING VORTEX OF A WING WITH WING-TIP BLOWING

Hock-Bin Lim Mar. 1994 136 p Sponsored by NASA. Ames Research Center

(NASA-CR-195803; NAS 1.26:195803; JIAA-TR-112) Avail: CASI HC A07/MF A02

Trailing vortices generated by lifting surfaces such as helicopter rotor blades, ship propellers, fixed wings, and canard control surfaces are known to be the source of noise, vibration, cavitation, degradation of performance, and other hazardous problems. Controlling these vortices is, therefore, of practical interest. The formation and behavior of the trailing vortices are studied in the present research. In addition, wing-tip blowing concepts employing axial blowing and spanwise blowing are studied to determine their effectiveness in controlling these vortices and their effects on the performance of the wing. The 3D, unsteady, thin-layer compressible Navier-Stokes equations are solved using a time-accurate, implicit, finite difference scheme that employs LU-ADI factorization. The wing-tip blowing is simulated using the actuator plane concept, thereby, not requiring resolution of the jet slot geometry. Furthermore, the solution blanking feature of the chimera scheme is used to simplify the parametric study procedure for the wing-tip blowing. Computed results are shown to compare favorably with experimental measurements. It is found that axial wing-tip blowing, although delaying the rolling-up of the trailing vortices and the near-field behavior of the flowfield, does not dissipate the circulation strength of the trailing vortex farther downstream. Spanwise wing-tip blowing has the effect of displacing the trailing vortices outboard and upward. The increased 'wing-span' due to the spanwise wing-tip blowing has the effect of lift augmentation on the wing and the strengthening of the trailing vortices. Secondary trailing vortices are created at high spanwise wing-tip blowing intensities. Author (revised)

AN ANALYTICAL STUDY OF UNSTEADY ROTOR/FUSELAGE INTERACTION IN HOVER AND FORWARD FLIGHT Ph.D. Thesis
Gilbert Lewis Crouse, Jr. 1992 265 p
Avail: Univ. Microfilms Order No. DA9315626

An analytical study of the coupled rotor/fuselage aerodynamic environment is presented. Results from the analysis are used to help understand the nature of interactional phenomena on helicopters. Two analytical methods have been developed, and results from these models are compared with experimental measurements on a representative rotor/body model. The first method is a simplified analysis that treats the fuselage as a planar surface. This model is very computationally efficient, and is particularly useful for studying the pressure on the upper surface of the fuselage induced by the rotor and its wake. The second, and more comprehensive, model is the MURFI (Maryland Unsteady Rotor/Fuselage Interaction) model and consists of an unsteady source panel representation of the fuselage coupled with a lifting line rotor model and several different wake models. This analysis is more computationally expensive than the simplified model, but is capable of studying the entire coupled rotor/fuselage flowfield. In addition, the latter model is also used for the prediction of the effects of the fuselage on the rotor flowfield. A new helicopter free-wake methodology is also presented. The new model overcomes the well known instability of traditional free-wake methods in hover and in low-speed flight. In addition, the new method achieves this capability without an appreciable increase in computational effort. This model is particularly useful for interactional aerodynamics since the most severe wake/fuselage interactions occur in the hover and low-speed flight regime. Using these analytical models, results are shown that clearly demonstrate the capability of potential flow analyses to predict interactional effects, provided that all of the pertinent unsteady terms are included in the analysis. In particular, it is shown that the unsteady terms due to the time-rate-of-change of the surface source elements are very important to prediction of the surface pressure response. The analysis has also provided an improved understanding of the effects of the fuselage on the rotor loads and performance. Dissert. Abstr.

TIME-MARCHING AEROELASTIC AND SPATIAL ADAPTATION PROCEDURES ON TRIANGULAR AND TETRAHEDRAL MESHES USING AN UNSTRUCTURED-GRID EULER METHOD Ph.D. Thesis
Russ David Rausch 1992 301 p
Avail: Univ. Microfilms Order No. DA9314067

Two- and three-dimensional, unstructured-grid, upwind-type Euler codes were modified to include time-marching aeroelastic and spatial adaptation procedures on triangular and tetrahedral meshes. The modifications for the time-marching aeroelastic procedures involve the addition of the structural equations of motion for their simultaneous time integration with the governing flow equations. A detailed description of the time-marching aeroelastic procedures is presented along with comparisons of computed results with experimental data to assess the accuracy of the capability. Flutter results are shown for both two and three-dimensional configurations including a NACA 0012 airfoil, an isolated 45 deg swept-back wing, and a supersonic transport configuration with a fuselage, clipped delta wing, and two identical rearward-mounted engine nacelles. The spatial adaptation procedures involve mesh enrichment and mesh coarsening to either add points in high gradient regions of the flow or remove points where they are not needed, respectively, in order to produce time-accurate solutions of high spatial accuracy at minimal computational cost. A detailed description of the enrichment and coarsening procedures is presented along with comparisons of computed results with experimental data to assess the accuracy of the capability. Steady results using the spatial adaptation procedures are shown for a NACA 0012 airfoil, an F-5 fighter wing, and an ONERA M6 wing. Unsteady results are shown for a NACA 0012 airfoil and a three dimensional simulation of a one-dimensional shock tube problem. The computed results are shown to be of high spatial accuracy, primarily in that shock waves are sharply captured. Dissert. Abstr.

UNSTEADY TRANSONIC AERODYNAMICS IN FREQUENCY DOMAIN FOR FLUTTER ANALYSIS Ph.D. Thesis
Tai-Hsing Tom Sun 1992 100 p
Avail: Univ. Microfilms Order No. DA9313180

A finite difference method for calculating the three dimensional nonlinear transonic flow in the frequency domain is presented for the solution of unsteady pressure distribution. The averaging technique is employed to separate the governing equation into the in-phase and the out-of-phase equations. These two equations are then solved simultaneously with the finite difference scheme adopted in an existing steady code. The modified code is verified by comparing the calculated results with experimental data and existing computational method for a uniform rectangular wing with NACA 64A010A airfoil, ONERA M6 wing, a uniform rectangular wing with symmetrical circular arc airfoil in pitching or structural bending oscillations. The results are shown in good agreement in most cases. The effects on the unsteady characteristics of grid number and convergence criterion are discussed. A new methodology for solving the nonlinear flutter condition is also discussed. The formulations using the Beecham-Titchner method shows that the flutter conditions can be easily determined. Dissert. Abstr.

PARTICLE KINETIC SIMULATION OF HIGH ALTITUDE HYPERVELOCITY FLIGHT Final Technical Report, 1 Jan. 1989 - 31 Jan. 1994
Iain Boyd and Brian L. Haas 19 Apr. 1994 17 p
(Contract NCC2-582)
(NASA-CR-194535; NAS 1.26:194535) Avail: CASI HC A03/MF A01

Rarefied flows about hypersonic vehicles entering the upper atmosphere or through nozzles expanding into a near vacuum may only be simulated accurately with a direct simulation Monte Carlo (DSMC) method. Under this grant, researchers enhanced the models employed in the DSMC method and performed simulations in support of existing NASA projects or missions. DSMC models were developed and validated for simulating rotational, vibrational, and chemical relaxation in high-temperature flows, including effects of quantized anharmonic oscillators and temperature-dependent relaxation rates. State-of-the-art advancements were made in simulating coupled vibration-dissociation recombination for post-shock flows. Models were also developed to compute vehicle surface temperatures directly in the code rather than requiring isothermal estimates. These codes were instrumental in simulating aerobraking of NASA's Magellan spacecraft during orbital maneuvers to assess heat transfer and aerodynamic properties of the delicate satellite. NASA also depended upon simulations of entry of the Galileo probe into the atmosphere of Jupiter to provide drag and flow field information essential for accurate interpretation of an onboard experiment. Finally, the codes have been used extensively to simulate expanding nozzle flows in low-power thrusters in support of propulsion activities at NASA-Lewis. Detailed comparisons between continuum calculations and DSMC results helped to quantify the limitations of continuum CFD codes in rarefied applications. Author

WALL PRESSURE FLUCTUATIONS IN THE REATTACHMENT REGION OF A SUPERSONIC FREE SHEAR LAYER Final Technical Report, 1 Jan. 1991 - 30 Jun. 1991

Alexander J. Smits 14 Apr. 1994 10 p

(Grant NAG1-1072)

(NASA-CR-195790; NAS 1.26:195790) Avail: CASI HC A02/MF A01

The primary aim of this research program was to investigate the mechanisms which cause the unsteady wall-pressure fluctuations in shock wave turbulent shear layer interactions. The secondary aim was to find means to reduce the magnitude of the fluctuating pressure loads by controlling the unsteady shock motion. The particular flow under study is the unsteady shock wave interaction formed in the reattachment zone of a separated supersonic flow. Similar flows are encountered in many practical situations, and they are associated with high levels of fluctuating wall pressure. The free shear layer is formed by the flow over a backward facing step, using an existing model, with the base pressure on the step adjusted so that there is no pressure discontinuity at the lip. The shear layer therefore develops in a zero pressure gradient. The primary advantage of this flow configuration is that the reattachment process can be studied in the absence of a separation shock. The mean flow data, and some preliminary hot-wire measurements of the mass-flux fluctuations were made by Baca and Settles, Baca, Williams and Bogdonoff, who showed that the shear layer became self-similar at about 17 delta(sub 0) downstream of the lip, and that it grew at a rate typical of the observed Mach number difference (about 1/3rd the incompressible growth rate). The turbulence measurements were later extended by Hayakawa, Smits and Bogdonoff under NASA Headquarters support. Derived from text

AERODYNAMIC CHARACTERISTICS OF A PROPELLER-POWERED HIGH-LIFT SEMISPAN WING

Garl L. Gentry, Jr., M. A. Takallu, and Zachary T. Applin Apr. 1994 70 p

(RTOP 535-03-10-02)

(NASA-TM-4541; L-17259; NAS 1.15:4541) Avail: CASI HC A04/MF A01

A small-scale semispan high-lift wing-flap system equipped under the wing with a turboprop engine assembly was tested in the LaRC 14- by 22-Foot Subsonic Tunnel. Experimental data were obtained for various propeller rotational speeds, nacelle locations, and nacelle inclinations. To isolate the effects of the high lift system, data were obtained with and without the flaps and leading-edge device. The effects of the propeller slipstream on the overall longitudinal aerodynamic characteristics of the wing-propeller assembly were examined. Test results indicated that the lift coefficient of the wing could be increased by the propeller slipstream when the rotational speed was increased and high-lift devices were deployed. Decreasing the nacelle inclination (increased pitch down) enhanced the lift performance of the system much more than varying the vertical or horizontal location of the nacelle. Furthermore, decreasing the nacelle inclination led to higher lift curve slope values, which indicated that the powered wing could sustain higher angles of attack near maximum lift performance. Any lift augmentation was accompanied by a drag penalty due to the increased wing lift. Author (revised)

AIRCRAFT AERODYNAMICS WITH DEFLECTED JETS IN GROUND EFFECT Ph.D. Thesis

Chyuan-Hsyan Paul Liaw 1992 116 p

Avail: Univ. Microfilms Order No. DA9313133

A computational method by combining a potential flow approach with a Navier-Stokes solver is developed to analyze the flow field and predict the aerodynamics for three-dimensional configurations with deflected jet in ground effect. The potential flow method, PMARC/VSAERO, is a low-order panel code solving the potential flow over three-dimensional geometries. The Navier-Stokes code (NS3D) is based on the vorticity transport equation and the Poisson equation for the vector velocity potential in viscous, incompressible flow. Calculations for a rectangular flat plate and a wing-body combination with a single normal-deflected jet in ground effect with and without free stream are conducted. The computed results indicate that due to the induced velocity of a constant-thrust jet, the suck-down force (-L) is increased when the ground height (h) decreases. Calculated results for a 90 degree lifting jet issuing from a flat plate and for a wing-body configuration show good agreement in trend with available data. The computed moment coefficient versus ground height is also compared with data for the wing-body configuration. It also shows a good agreement in trend. However, the magnitude of the suck-down effect is under predicted. The discrepancy between the computational results and the experimental data is most likely due to a lack of an accurate simulation of turbulence effect, a fine enough grid system, an accurate specified vorticity distribution at the jet exit, or unknown experimental errors. The calculated flow field of roll-up jets is also presented. The flow patterns of a 90 degree jet impinging on the ground without the free stream effect has a stagnation point on the ground and symmetric with respect to the jet core. Due to the effect of the free stream, the stagnation point occurs ahead of the jet core, and the flow pattern is no longer symmetric. For deflected jets with any deflection angle other than 90 degrees, the vortex roll-up is stronger in the direction of the jet deflection, and the vortex shape is deformed. With a free stream combined with deflected jet, the flow pattern becomes more complicated. The jet core is deformed and the vortex roll-up is obvious. For lower ground height, the vortex becomes flatter. In summary, the flow patterns are affected by jet velocity, free stream velocity, deflected angles and ground height. Dissert. Abstr.

THE 3-D LDV MEASUREMENTS ON A 30-DEGREE SWEPT WING WITH A SIMULATED ICE ACCRETION Final Report

Michael B. Bragg and Michael K. Kerho Apr. 1994 63 p

(Grant NAG3-1134; RTOP 505-68-10)

(NASA-CR-195327; E-8778; NAS 1.26:195327) Avail: CASI HC A04/MF A01

Three dimensional flowfield measurements have been obtained for a semispan 30-degree swept wing with a simulated glaze ice accretion. The model tested has a NACA 0012 section perpendicular to the leading edge. Measurements were made using a two-component laser Doppler velocimeter (LDV) system. Mean velocity measurements were obtained for all three velocity components. Streamwise turbulence intensities were also obtained. All measurements were taken in the University of Illinois 3 by 4 foot subsonic wind tunnel at a Reynolds number of 1 million and 8 degrees angle of attack. The data is presented in tabular form. COMPUTATION OF WIND TUNNEL WALL EFFECTS FOR COMPLEX MODELS USING A LOW-ORDER PANEL METHOD

Dale L. Ashby and Scott H. Harris Feb. 1994 19 p

(RTOP 505-59-53)

(NASA-TM-104019; A-93077; NAS 1.15:104019) Avail: CASI HC A03/MF A01

A technique for determining wind tunnel wall effects for complex models using the low-order, three dimensional panel method PMARC (Panel Method Ames Research Center) has been developed. Initial validation of the technique was performed using lift-coefficient data in the linear lift range from tests of a large-scale STOVL fighter model in the National Full-Scale Aerodynamics Complex (NFAC) facility. The data from these tests served as an ideal database for validating the technique because the same model was tested in two wind tunnel test sections with widely different dimensions. The lift-coefficient data obtained for the same model configuration in the two test sections were different, indicating a significant influence of the presence of the tunnel walls and mounting hardware on the lift coefficient in at least one of the two test sections. The wind tunnel wall effects were computed using PMARC and then subtracted from the measured data to yield corrected lift-coefficient versus angle-of-attack curves. The corrected lift-coefficient curves from the two wind tunnel test sections matched very well. Detailed pressure distributions computed by PMARC on the wing lower surface helped identify the source of large strut interference effects in one of the wind tunnel test sections. Extension of the technique to analysis of wind tunnel wall effects on the lift coefficient in the nonlinear lift range and on drag coefficient will require the addition of boundary-layer and separated-flow models to PMARC. AN EXPERIMENTAL STUDY OF THE AERODYNAMICS OF A SWEPT AND UNSWEPT SEMISPAN WING WITH A SIMULATED GLAZE ICE ACCRETION Final Report

Michael B. Bragg May 1994 232 p

(Grants NAG3-1134; NAG3-28; RTOP 505-68-10)

(NASA-CR-195330; E-8813; NAS 1.26:195330) Avail: CASI HC A11/MF A03

Two semispan wings, one with a rectangular planform and one with 30 degrees of leading edge sweep were tested. Both had a NACA 0012 airfoil section, and both were tested clean and with simulated glaze ice shapes on their leading edges. Several surface roughness were tested. Each model geometry is documented and each surface roughness is explained. Aerodynamic performance of the wing in the form of sectional lift and integrated three-dimensional lift is documented through pressure measurements obtained from rows of surface pressure taps placed at five span locations on the wing. For the rectangular wing, sectional drag near the midspan is obtained from wake total pressure profiles. The data is presented in tabular and graphical form and is also available on computer disk. USER'S MANUAL FOR THE MODEL INTERFACE AND PLUGBOARD CABINETS IN THE 14- BY 22-FOOT SUBSONIC TUNNEL

Robert B. Askew and P. Frank Quinto Apr. 1994 55 p

(RTOP 505-59-10-13)

(NASA-TM-109062; NAS 1.15:109062) Avail: CASI HC A04/MF A01

The primary method of connection between the wind tunnel model instrumentation and the data acquisition system in the 14- by 22-Foot Subsonic Tunnel is through the Model Interface (MIF) and Plugboard cabinets. The MIF and Plugboard cabinets allow versatility in the connection of the instrumentation to the different data systems in the facility. The User's Manual describes the components inside the MIF cabinet, the input and output of the MIF, and the MIF patchboard, and the Plugboard cabinets. There are examples of standard connections for most of the instrumentation used in the facility. Author (revised)

(PB94-125598; NLR-TP-92190-UP; AIAA Paper 92-2619-CP; Alenia-TR-57X92054; CIRA-DLC-EST-271; ETN-94-95581) Avail: CASI HC A03

For industrial calculations of three dimensional flows around transport aircraft, a system of Computational Fluid Dynamics (CFD) codes for flow calculations is developed. This system includes codes for aerodynamic geometry modeling in block decomposition work, multiblock grid generation, Euler and Navier-Stokes flow calculations, and flow visualization. The codes are tuned to each other. Two examples of this tuning are discussed. Analytic representations for geometric shapes of aerodynamic curves and surfaces are presented that may be used for several tasks in CFD work (geometric modeling of surface, refacing of aerodynamic configuration surfaces). Multiblock grid generation is simplified by allowing grid lines to be only C(sup 0)- continuous over block faces. Block coupling algorithms for the flow solvers are discussed, that prevent accuracy loss due to the nonsmoothness of the grid over block faces. ESA

NUMERICAL INVESTIGATION INTO HIGH-ANGLE-OF-ATTACK LEADING-EDGE VORTEX FLOW

J. I. vandenBerg, H. W. M. Hoeijmakers, and H. A. Sytsma 26 May 1992 29 p Presented at the AIAA 10th Applied Aerodynamics Conference, Palo Alto, CA, 22-24 Jun. 1992 See also N92-45477 Sponsored by Netherlands Agency for Aerospace Programs Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-125564; NLR-TP-92248-U; AIAA Paper 92-2600-CP; ETN-94-95584) Avail: CASI HC A03

A Euler method is applied to the steady subsonic (M(infinity) = 0.50) leading edge vortex flow about a 65 deg sharp edged cropped delta wing at incidences close to the incidence at which vortex breakdown is observed in wind tunnel experiments. Above a critical value of the incidence the pseudo time dependent numerical procedure fails to attain a steady state solution. This occurrence of 'solution breakdown' indicates the limits of the domain of applicability of the steady flow Euler method for the case of subsonic leading edge vortex flow. Analysis of the converged solution at incidences just below the critical value reveals that above the aft part of the wing the velocity and vorticity distribution within the vortex core undergo a remarkable change. CALCULUS OF VARIATIONS APPLIED TO 2D MULTI-POINT AIRFOIL DESIGN

T. E. Labrujere and J. vanderVooren 1 Sep. 1992 32 p Presented at the 1st European Computational Fluid Dynamics Conference, Brussels, Belgium, 7-11 Sep. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-125457; NLR-TP-92361-U; ETN-94-95594) Avail: CASI HC A03

Aspects of a residual correction method to solve the multipoint airfoil design problem for subsonic and transonic conditions are discussed. The method is based on full potential theory and minimizes a cost function weighting the deviations from specified target pressure distributions for each design condition in a least squares sense. Deviations from specified target pressure distributions (residuals) are translated into airfoil geometry corrections, using an approximate inverse method derived from solving an equivalent incompressible multipoint airfoil design problem using calculus of variations and numerical optimization. The feasibility of introducing the equivalent incompressible multipoint design problem is demonstrated for a two point reconstruction test case. First results of a two point example design are presented. ESA

ASPECTS OF THE MODELING AND NUMERICAL SIMULATION OF LEADING-EDGE VORTEX FLOW

H. W. M. Hoeijmakers 4 Dec. 1992 23 p Presented at the IUTAM Symposium on Fluid Dynamics of High Angle of Attack, Tokyo University, Japan, 13-17 Sep. 1992 Sponsored by Netherlands Agency for Aerospace Programs Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B179108; NLR-TP-92521-U; ETN-94-95965) Avail: CASI HC A03

A cell centered central difference finite volume Euler method is applied to the steady subsonic flow about a 65 degree sharp cropped delta wing at incidences close to the incidence at which leading edge vortex breakdown

is observed in wind tunnel experiments. Above a critical value of the incidence the pseudo-time dependent numerical procedure fails to attain a steady state solution. For the case of subsonic leading edge vortex flow the occurrence of 'solution breakdown' indicates the limits of the domain of applicability of the steady flow Euler method. In the search for the critical incidence it is found that for a given grid and for a given setting of the parameters controlling the artificial dissipation two distinct, steady state solutions exist. Analysis of the two solutions obtained at one incidence reveals that within the vortex core above the aft part of the wing these solutions feature remarkably different velocity and vorticity ditributions. SENSITIVITY ANALYSIS OF THE STATIC AEROELASTIC RESPONSE OF A WING Ph.D. Thesis

Lloyd Byron Eldred 1993 147 p

Avail: Univ. Microfilms Order No. DA9319768

A technique to obtain the sensitivity of the static aeroelastic response of a three dimensional wing model is designed and implemented. The formulation is quite general and accepts any aerodynamic and structural analysis capability. A program to combine the discipline level, or local, sensitivities into global sensitivity derivatives is developed. A variety of representations of the wing pressure field are developed and tested to determine the most accurate and efficient scheme for representing the field outside of the aerodynamic code. Chebyshev polynomials are used to globally fit the pressure field. This approach had some difficulties in representing local variations in the field, so a variety of local interpolation polynomial pressure representations are also implemented. These panel based representations use a constant pressure value, a bilinearly interpolated value, or a biquadratically interpolated value. The interpolation polynomial approaches do an excellent job of reducing the numerical problems of the global approach for comparable computational effort. Regardless of the pressure representation used, sensitivity and response results with excellent accuracy have been produced for large integrated quantities such as wing tip deflection and trim angel of attack. The sensitivities of such things as individual generalized displacements have been found with fair accuracy. In general, accuracy is found to be proportional to the relative size of the derivatives to the quantity itself. Dissert. Abstr.

PROSPECTS OF TIME-LINEARIZED UNSTEADY CALCULATION METHODS FOR EXPONENTIALLY DIVERGING MOTIONS IN AEROELASTICITY

M. H. J. Hounjet and B. J. G. Eussen 22 Apr. 1992 21 p Presented at the AIAA Dynamics Specialist Conference, Dallas, TX, 16-17 Apr. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-126224; NLR-TP-92163; ETN-94-95578) Avail: CASI HC A03

A demonstration is given of a simple procedure which was used to generate unsteady loads for oscillating wings in a two dimensional and three dimensional subsonic, transonic and supersonic flow for an almost complete range of existing time linearized methods including a method allowing for wind tunnel wall interference. The method transforms real unsteady data obtained for diverging exponential motions of the wind to unsteady complex data for harmonic oscillations by means of fitting the real data by Pade polynomials and using these approximations for harmonic oscillations assuming the analytical continuation is valid. GRID ADAPTION IN COMPUTATIONAL AERODYNAMICS

R. Hagmeijer and K. M. J. deCock 1 Apr. 1992 23 p Submitted for publication Sponsored in part by National Aerospace Lab. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract AERO-0018-C(H))

(PB94-126240; NLR-TP-92139-U; ETN-94-95575) Avail: CASI HC A03

An algorithm to adapt computational grids is applied to aerodynamic problems. The algorithm is described and the main features are discussed. Applications to both inviscid and viscous flows around two dimensional airfoils show that the algorithm is robust and almost fully automatic, and that shocks, expansion zones, boundary layers and shear layers are well resolved by the adapted grid. HOPF BIFURCATION IN VISCOUS, LOW-SPEED FLOWS ABOUT AN AIRFOIL WITH STRUCTURAL COUPLING Ph.D. Thesis

Mark John Lutton 1993 152 p

Avail: Univ. Microfilms Order No. DA9324933

The locations of Hopf bifurcation points associated with the viscous incompressible flow about a NACA 0012 airfoil with structural coupling are computed for very low Reynolds numbers (less than 2000). A semi-implicit, first-order-accurate time-integration algorithm is employed to solve the streamfunction-vorticity form of the Navier-Stokes equations. The formulation models the inclusion of simple structural elements affixed to the airfoil and captures the resulting airfoil motion. The equations describing the airfoil motion are integrated in time using a fourth-order Runge-Kutta algorithm. The dissertation is divided into two parts. In Part 1, numerical experiments are performed in the laminar regime to determine if the structural model of the airfoil has an effect upon the location of the Hopf bifurcation point when compared with the fixed airfoil. Results are reported for a variety of structural characteristics, including variation of torsional and linear spring constants, inertial properties, structural coupling, and structural damping. The structure of the solution space is explored by means of phase plots. In Part II, the Baldwin-Lomax turbulence model is implemented to model turbulent flow. A numerical effort is made to predict the onset of unsteady flow and the results are compared to theory and experiment. A comparison is undertaken with the compressible and incompressible form of the Navier-Stokes equations to assess the correspondence of the unsteady lift evolved by pitching the airfoil at a prescribed frequency and amplitude. Comparisons are made with the lift predicted by the potential flow method of Theodorsen. Dissert. Abstr.

NUMERICAL SIMULATION OF LEADING-EDGE VORTEX FLOW

H. W. M. Hoeijmakers (Technische Univ., Eindhoven, Netherlands.) 30 Nov. 1991 31 p Sponsored by Netherlands Agency for Aerospace Programs, and Ministry of Defence Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B175154; PB94-125481; NLR-TP-91471-U; ETN-94-95568) Avail: CASI HC A03

An analysis of results of a computational method to simulate the steady compressible vortical type of flow around a 65 deg sharp edged cropped delta wing is presented. Some more fundamental aspects of the numerical simulation such as the separation of the flow, the structure of the leading edge vortex core and the flow inside the free shear layer are emphasized. For the vortex core in isolation as well as for the free shear layer, closed form solutions are presented which might assist in the analysis of the numerical results. ESA

AERODYNAMIC ANALYSIS OF SLIPSTREAM/WING/NACELLE INTERFERENCE FOR PRELIMINARY DESIGN OF AIRCRAFT CONFIGURATIONS
C. M. vanBeek, W. J. Piers, and B. Oskam 22 Nov. 1991 25 p Presented at the AGARD Fluid Dynamics Panel Symposium on Aerodynamic Engine/Airframe Integration for High Performance Aircraft and Missiles, Fort Worth, TX, 7-10 Oct. 1991 Sponsored by Netherlands Agency for Aerospace Programs
(AD-B173651; NLR-TP-91453; ETN-94-95567) Avail: CASI HC A03/MF A01

A panel method based model for the computation of the time averaged influence of a propeller slipstream on the aerodynamic characteristics of an aircraft configuration is described. The slipstream model is based on the simplifications that the single rotating propeller is replaced by an actuator disk and that all the vorticity of the slipstream is represented on a cylindrical sheet of fixed geometry which envelops the slipstream in combination with a discrete vortex at the axis of the slipstream. Appropriate jump conditions across the actuator disk and boundary conditions on the cylindrical sheet, solved simultaneously with the boundary conditions on the aircraft configuration, yield the mutual influence of the propeller and the slipstream on the aerodynamic characteristics of the aircraft. This slipstream model is incorporated in a three dimensional panel method. Computed lift increments due to the slipstream are presented for a realistic wing/nacelle/fuselage configuration and compared with wind tunnel data for several thrust coefficients and angles of attack of the aircraft. EVALUATION OF FLIP-FLOP JET NOZZLES FOR USE AS PRACTICAL EXCITATION DEVICES
Ganesh Raman (NYMA, Inc., Brook Park, OH.), Edward J. Rice, and David M. Cornelius Apr. 1994 13 p Proposed for presentation at the ASME Fluids Engineering Division Summer Meeting, Lake Tahoe, NV, 19-23 Jun. 1994; sponsored by ASME
(Contract NAS3-27186; RTOP 505-62-52)
(NASA-TM-106377; E-8190; NAS 1.15:106377) Avail: CASI HC A03/MF A01

This paper describes the flowfield characteristics of the flip-flop jet nozzle and the potential for using this nozzle as a practical excitation device. It appears from the existing body of published information that there is a lack of data on the parameters affecting the operation of such nozzles and on the mechanism of operation of these nozzles. An attempt is made in the present work to study the important parameters affecting the operation and performance of a flip-flop jet nozzle. Measurements were carried out to systematically assess the effect of varying the nozzle pressure ratio (NPR) as well as the length and volume of the feedback tube on the frequency of oscillation of this device. Flow visualization was used to obtain a better understanding of the jet flowfield and of the processes occurring within the feedback tube. The frequency of oscillation of the flip-flop jet depended significantly on the feedback tube length and volume as well as on the nozzle pressure ratio. In contrast, the coherent velocity perturbation levels did not depend on the above mentioned parameters. The data presented in this paper would be useful for modeling such flip-flop excitation devices that are potentially useful for controlling practical shear flows. Author

CRASHWORTHINESS ANALYSIS OF COMMUTER AIRCRAFT SEATS Technical Note
David H. Laananen Nov. 1993 20 p
(Contract DTFA03-90-P-00447)
(AD-A275889; CR-R-91012; DOT/FAA/CT-TN-91/28) Avail: CASI HC A03/MF A01

During the past several years, the Federal Aviation Regulations (FAR) were significantly modified with respect to seat/restraint system strength, attachment of seats to the aircraft structure, and the means by which they are to be evaluated. Aircraft accident data, human tolerance levels, and aircraft structural characteristics have been considered in the development of these new standards. Dynamic testing is now required for seats to be installed in general aviation aircraft, transport category aircraft, and rotorcraft. Performance criteria are similar to those specified by the Federal Motor Vehicle Safety Standards for automobiles but also include a limit on pelvic force, in order to prevent spinal injuries which may be caused by the vertical component of impact force. A category of aircraft that has not as yet been affected by the rule modifications is the commuter type aircraft, which seats 10 to 19 passengers. Since this airplane is closer in size to general aviation aircraft than to large transports, it is also covered by FAR Part 23. The Federal Aviation Administration is currently involved in the conduct of a test program addressing commuter aircraft occupant crash safety. In support of this effort, a research program the includes full-scale aircraft drop tests, sled tests of seats, and computer simulations is being conducted. This report describes the use of the SOM-LA (Seat/Occupant Model-Light Aircraft) program in modeling three commuter aircraft seats. The predicted response of the seats to a potential set of test conditions is described. DTIC

POTENTIAL HAZARDS OF MAGNETIC RESONANCE IMAGERS TO EMERGENCY MEDICAL SERVICE HELICOPTER OPERATIONS Final Report
Robert B. Newman Jan. 1993 56 p
(Contract DTFA01-87-C-00014)
(DOT/FAA/RD-92/15; SCT-92RR-14) Avail: CASI HC A04/MF A01

In recent years, there have been several incidents with helicopters where magnetic resonance imagers (MRI's) have interferred with the operation of magnetic sensors such as compasses and directional gyroscopes. The magnetic fields generated by the MRI magnet causes magnetic sensors to give aberrant readings. This report documents the characteristics of MIR's and how they operate. It discusses relevant federal regulations of MRI and all magnetic effects and hazards involved with operating helicopters in a strong static magnetic field for both personnel and equipment. Finally, the report makes recommendations for safe helicopter operations in and around MRI's. Author

A CAPACITY PLANNING MODEL FOR CANADIAN MILITARY AIRLIFT REQUESTS M.S. Thesis

Barry Anthony Stannard Aug. 1993 150 p

(ISBN-0-315-86079-0; CTN-94-61178) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The problem of the constrained assignment of n variable length tasks (missions), integrating many airlift requests from 13 users with eight priorities, to m parallel machines (CC130 Hercules airframes) is presented. A general mathematical model was developed which is suitable for assisting airlift planners in deciding which airlift mission requests to accept. The model can be implemented on a microcomputer and is essentially a computational subroutine for a larger decision support system. A high quality airlift capacity plan resulted from the application of a group of management science techniques. Analytic hierarchy process was used to quantify each mission request. A sequential linear programming model proved to be a computationally efficient approach for producing an automated planning aid to assist the airlift capacity planners. The model is flexible, computationally fast, and accurate. It handles linked missions, either as a pair or as a minimum out of an optimal number. User hour and fleet flying hour constraints are modelled and missions can be added, deleted, or modified. While the model was developed for the Canadian Forces, it can be adapted for other similar military and civilian situations. Author (CISTI)

From Jan. 15 through Mar. 31, 1991, the National Oceanic and Atmospheric Administration's (NOAA) Wave Propagation Laboratory (WPL) participated in the Winter Icing and Storms Project (WISP91). Several remote sensors were used in the study: an array of four dual-channel microwave radiometers, Wind Profilers and Radio Acoustic Sounding Systems (RASS) at 915, 405, and 50 MHz; operational National Weather Service (NWS) lidar ceilometers; and infrared radiometers operating at 10.6 micrometers. One of the principal objectives of the project was to determine the utility of combined sensors to detect supercooled liquid water. After describing the changes in the system relative to the 1990 experiments, results of two representative cases are presented to illustrate the capabilities and limitations of the combined system. EVALUATION OF ACCESS/NAVIGATIONAL FEATURES OF A GRAPHICAL-USER INTERFACE INSTALLED ON A PORTABLE MAINTENANCE AID M.S. Thesis

Lisa A. Carney and Roger A. Quinto Sep. 1993 146 p

(AD-A275791; AFIT/GLM/LAL/93S-9) Avail: CASI HC A07/MF A02

Portable maintenance aids (PMA's) are being developed to access and store electronic technical information on the flightline. The prototype PMA designed by Armstrong Laboratory personnel has redundant access/navigational features. Redundancy increases software memory usage and adds unnecessary weight to the PMA. The purpose of this research was to determine the best access/navigational feature installed on the PMA. The best feature is the feature that provides the highest degree of user satisfaction. An experiment was conducted to evaluate the following features for screen and menu access and navigation, respectively: dedicated/hardware keys, programmable soft keys, and push button keys, and number keys, cursor control keys, and programmable soft keys. Modified computer screens from the prototype PMA were used on a laptop personal computer, which simulated the PMA, to evaluate each feature, one at a time. Twenty-eight maintenance technicians rated and ranked each access/navigational feature. The results indicated that the best feature for screen access and navigation was the dedicated/hardware keys and the best feature for menu access and navigation was the number keys. DTIC

LOS ANGELES INTERNATIONAL AIRPORT INSTRUMENT LANDING SYSTEM APPROACH DATA COLLECTION AND REDUCTION, PHASE 1 Final Repoort, Nov. 1991 - Apr. 1992

J. Thomas, D. Timoteo, and P. Hoang Nov. 1993 72 p

(AD-A275115; DOT/FAA/CT-TN93/12) Avail: CASI HC A04/MF A01

Position data on aircraft flying Instrument Landing System (ILS) approaches from 40 nautical miles (nmi) down to runway threshold were collected at Los Angeles International Airport (LAX) between November 26, 1991 and April 25, 1992. The purpose of the data collection was to provide an accurate database of navigational performance of aircraft flying ILS approaches at distances between 10 nmi and 32 nmi. Aircraft position data were collected using the in-place LAX surveillance primary and secondary radars. The data were reduced and analyzed at the Federal Aviation Administration (FAA) Technical Center by ACD-340 personnel. The discussion in this Final Report concerns the accuracy of the collected position data and possible sources of error in the data collection. DTIC

THE 1993 FEDERAL AVIATION ADMINISTRATION AVIATION SYSTEM CAPITAL INVESTMENT PLAN

Dec. 1993 304 p

Avail: CASI HC A14/MF A03

Based on a total system approach, the Aviation System Capital Investment Plan (CIP) relates user community needs to technical opportunities, human factors, and operational considerations. The systematic implementation of the projects defined in this CIP will result in improved safety and efficiency, while accommodating spiraling demands at constrained cost. It supports a more complex system and creates a foundation for continued evolution that uses modern technologies and capabilities. The CIP also recognizes that continuing upgrades and enhancements are necessary to meet evolving national airspace system (NAS) user needs. It includes the following: Original NAS Plan (Chapter 2)--Preservation of the original NAS Plan projects; Growth (Chapter 3)--Projects that expand, relocate, or consolidate existing facilities/capabilities in response to changing demand on the system. Each potential metroplex control facility (MCF) is identified in this chapter; Infrastructure Replenishment (Chapter 4)--Projects identified since the original NAS Plan that refurbish structures, replace obsolete equipment, or relocate facilities to maintain service, improve effectiveness, and/or reduce cost; Supportability (Chapter 5)--Capital improvement projects that support logistics, provide spares, train personnel, and manage the human resource aspect of modernizing the NAS; and New Capabilities (Chapter 6)--Projects identified since the original NAS Plan which, if implemented, are expected to add significant new capabilities to the system. The new TRACON Automation System project is contained in this chapter. Author (revised)

ADVANCES IN DEVELOPMENT CAPABILITIES FOR INTELLIGENT AIR TRAFFIC MANAGEMENT SYSTEMS

Kerry M. Levin and John J. Fearnsides *In* AGARD, Machine Intelligence in Air Traffic Management Oct. 1993 18 p (For primary document see N94-29558 08-04)

Copyright Avail: CASI HC A03/MF A04

Visual presentation is a major source of information for air traffic control. Significant advances in computers, display technology, and the tools used by developers of intelligent air traffic management (ATM) systems pose challenges for the development of computer-human interfaces (CHI's) associated with the new automation. The CHI must be designed to be both usable and suitable. This paper reviews three capabilities available to developers of intelligent ATM systems: case-based reasoning system design, rule-based system design, and individually tailored CHI. It recommends that any intelligent ATM system be examined early in its development cycle in a laboratory environment, where it can be tested in concert with other elements of the ATM system. Author

Complete automation of an air traffic control system requires the identification of functions and their allocation to a distributed system, part of which is on the ground and part of which flies. The evolution of current systems appears to be taking place with ill-defined visions of what the final system will or should look like. In some cases this fuzzy view of the future is purposely carried because of the implications of proposing a view which antagonizes various groups or associations representing those already engaged in the process. Yet, each step along the way implies explicitly or implicitly some final target system. As each year goes by, we move toward a system which may be a long way from what is really desirable in the next century. It seems reasonable that some versions of the ideal future system should be understood within the community. At least one of these options should be what is technically feasible. From this, an acceptable system can be negotiated. The first step in this process is to determine the desired functionality without regard to any other factors. From this, technical feasibility can be determined and/or predicted; and finally, the allocation of the functions to humans or machines can be debated. The management of a dense cluttered air space requires a set of skills and capabilities on the part of an air traffic control team which, in some of their functions, cannot be represented algorithmically. Successful automated air traffic management systems will necessarily emulate the intuitive portions of the human management capability using various technologies drawn from the broad field of artificial intelligence. Indeed portions of the overall management system have been the subject of research and development efforts in many laboratories around the world. The integration of these fragments into an overall scheme is often left as an implicitly understood architecture. This paper begins by presenting CompEngServ (CES) Ltd.'s view of an automated airspace management system. The paper then presents an overview of the prototype of an advanced controller workstation developed by CES (under contract to Transport Canada) which prototypes various portions of this architecture for Airspace Management. This system represents the state of the art in Air Traffic Control (ATC) research. This prototype is also an example of multiple hardware and software technologies being harnessed to develop a solution to a problem initially thought to be too complex for automation. The paper then presents the future direction of research at CES and then closes with the issues which have been raised by our work that need addressing before an automated system will be practical. The CENA is in charge of studies related to Air Traffic Management and therefore to some of the communication, navigation, and surveillance means. The work is carried out to support French and European ATC (air traffic control) in an international cooperation. It encompasses studies and experimental development aiming at operational implementation within the CAUTRA 5 program. The different CENA projects are integrated in an experimental simulator frame named ADER. This test-bed will support one of the demonstrations within PHARE, a joint European experimental program. The CENA organization is based upon a technical directorate in charge of the horizontal projects as previously described and 10 divisions located either at Athis-Mons (near Paris) or in Toulouse. One of these divisions, called COA (Control Organization and Automation), deals mainly with studies aiming at providing ATM (air traffic management) operators with helpful decision tools, using advanced methods and technologies. In this paper, it can be found a short description of COA division activities and a more precise analysis of one of the projects, called GOETHE, aiming to provide ATFM (Air Traffic Flow Management) regulators with a more user-friendly tool. The major challenge facing the world's aircraft/airspace system (AAS) today is the need to provide increased capacity, whilst reducing delays, increasing the efficiency of flight operations, and improving safety. Technologies are emerging that should improve the performance of the system, but which could also introduce uncertainty, disputes, and inefficiency if not properly implemented. The aim of our research is to apply techniques from intelligent control theory and decision-making theory to define an Intelligent Aircraft/Airspace System (IAAS) for the year 2025. The IAAS would make effective use of the technical capabilities of all parts of the system to meet the demand for increased capacity with improved performance. Author

The Global Positioning System NAVSTAR is rapidly becoming the world standard for navigation and timing. Although primarily designed to be a military system, the civil user community is expanding at a breathtaking pace. After an introduction to the general GPS policies and the technical fundamentals this paper presents an idea on how to use GPS NAVSTAR to improve Air Traffic Control. Existing selective identification features will form the key to a GPS-based position, velocity, and acceleration message. Higher update rates and the vastly improved information on each aircraft will provide the input for a flight plan correlation function enabling an automatic air traffic monitoring and control far beyond current standards. Air traffic in Central Europe is dramatically increasing today. There are some indications that present upgrades of the air traffic control system might not be efficient and that planned upgrades will not be realized in time due to budgetary restrictions. One key element in air traffic control is a precise navigation of the aircraft during landing, the most critical part of the flight. It is presently performed by use of the instrument landing system ILS and in some areas already by the microwave landing system MLS. The latter provides a very high navigation performance and allows a high landing sequence under all weather conditions. However, it requires extensive ground equipment at the airports and hence, only a few airports in Central Europe are equipped with it today. This paper presents the results of a study on a new microwave landing system with a spaceborne radar transmitter and airborne radar receivers. Based on this bistatic radar system, navigation in landing phase could also be performed independently from weather conditions. However, it does not require any active equipment at the landing site. Even taxi way guidance could be performed with this system. It is called 'Ground Independent Landing System' (GILS). Author

The actual implemented Air Traffic Control (ATC) systems have radar coverage gaps on the Northern Atlantic and Trans-Siberian Routes as well as in the Pacific area. This situation results in insufficient air traffic surveillance information in the corresponding control sectors and larger separation between aircraft on these routes to ensure safe operation. Unfortunately, this procedure reduces the capacity and limits air traffic flow. These problems can be overcome by the worldwide use of the high accurate position data from Global Navigation Satellite Systems (GNSS) such as the U.S. Global Positioning System (GPS) and the Russian Global Navigation System (GLONASS) aboard the aircraft as proposed by the ICAO-FANS plan. In combination with the Automatic Dependent Surveillance (ADS) function as specified by ARINC 745, the onboard computed position and flight path data is transmitted to the Aeronautical Telecommunication Network (ATN) for further use by ATM and ATC. Based on these principles, Deutsche Aerospace AG, Airborne Systems Division has developed a demonstrator. This system integrates the precise (Differential) GNSS information with the data from an Inertial Measurement Unit (e.g. AHRS) aboard the demonstrator aircraft to fulfill the accuracy and consistency/integrity requirements during all phases of flight. This system integration has been done to ensure integrity of GNSS position information during satellite outages or satellite masking, e.g. during turns. For demonstrating ADS-functionality, the onboard computed position and flight path velocity is transmitted in combination with flight management information to the ground system using a data link. In addition to this en-route ADS function with medium accuracy requirements, a high accuracy mode using Differential GNSS data for conflict detection calculations between low separated aircraft has been implemented. The conflict detection and alert functions are based on a special designed Expert System capable of real time operation. A taxi monitoring function can also be performed by the system. All system functions have been tested and demonstrated during flight trials using a VHF data link for communication. Results of these flight tests will be presented. Author (revised)

The increasing sophistication of surveillance systems, both civilian and military, has generated a great deal of interest in techniques of multi-target tracking and sensor integration. To help SHAPE and the NATO Air Command and Control System (ACCS) Management Agency (NACMA) to specify and implement the ACCS surveillance subsystem, in particular in the areas of data fusion and identification, the SHAPE Technical Center (STC) is currently developing an ACCS Surveillance Exploratory Prototype (ASEP) as an element of its new integrated testbed. The purpose of the ASEP is to demonstrate the feasibility and operational benefits of future air picture generation systems. The significant difference between this advanced system and currently available systems is that ASEP will provide better tracking continuity, more accurate estimates of track positions, velocity, acceleration, and additional information on targets. The provision of this information on air targets is also of great importance for civil ATC systems, especially in view of growing requirements for ATC planning, conflict alert and conflict resolution. The use of multiple sensors and sources requires the fusion of different types of data, including sensor reports containing measured attributes such as the target type and other target features. Since advanced fusion algorithms are using kinematic data as well as attribute data for the identification process, the majority of all air targets can be identified automatically. This paper gives an overview of the following components that are implemented in the ACCS Surveillance Exploratory Prototype at STC: scenario generation and sensor simulation; real-time multi-sensor tracking; real-time radar data integration; external track and flight plan data integration; and air picture presentation on a Surveillance Workstation using new human-computer interface (HCI) techniques. Enhancement of air traffic capacity within the TMA cannot be achieved easily. Single solutions and improvements of technical equipment, procedures and standards, with automation support for human operators in isolated areas, e.g. for the management of the airport, airspace and Air Traffic Control very often will only yield marginal capacity increases. Whether it is: new concrete (runways, taxiways, aprons), reduced separation minima, or advanced ATM functions, all these measures will only result in significant capacity increases, if they are designed, developed and implemented in a comprehensive, combined effort, making use of set of complementary measures and functions in a well structured, optimized architecture and implementation strategy. This comprehensive approach is especially true for high density TMA's/airports, operating close to capacity limits, where any capacity enhancement measure will directly affect and/or require capacity related issues in other areas. Based upon the specific needs of the Frankfurt airport and TMA, DLR is working on a variety of tools and functions, which--combined and implemented in a well designed strategy plan--can yield significant capacity increases without the construction of new runways. Three candidate systems--under development or even already in operation--which mutually depend on and complement one another will be presented as examples of an even larger capacity enhancement plan for the TMA. A system for the automated management and control of terminal area traffic, referred to as the Center-TRACON Automation System (CTAS), is being developed at NASA Ames Research Center. In a cooperative program, NASA and FAA have efforts underway to install and evaluate the system at the Denver area and Dallas/Ft. Worth area air traffic control facilities. This paper will review CTAS architecture, and automation functions as well as the integration of CTAS into the existing operational system. CTAS consists of three types of integrated tools that provide computer-generated advisories for both en-route and terminal area controllers to guide them in managing and controlling arrival traffic efficiently. One tool, the Traffic Management Advisor (TMA), generates runway assignments, landing sequences and landing times for all arriving aircraft, including those originating from nearby feeder airports. TMA also assists in runway configuration control and flow management. Another tool, the Descent Advisor (DA), generates clearances for the en-route controllers handling arrival flows to metering gates. The DA's clearances ensure fuel-efficient and conflict free descents to the metering gates at specified crossing

times. In the terminal area, the Final Approach Spacing Tool (FAST) provides heading and speed advisories that help controllers produce an accurately spaced flow of aircraft on the final approach course. Data bases consisting of several hundred aircraft performance models, airline preferred operational procedures, and a three dimensional wind model support the operation of CTAS. The first component of CTAS, the Traffic Management Advisor, is being evaluated at the Denver TRACON and the Denver Air Route Traffic Control Center. The second component, the Final Approach Spacing Tool, will be evaluated in several stages at the Dallas/Fort Worth Airport beginning in October 1993. An initial stage of the Descent Advisor tool is being prepared for testing at the Denver Center in late 1994. Operational evaluations of all three integrated CTAS tools are expected to begin at the two field sites in 1995. Derived from text

In order to be able to investigate various aspects of the complex Air Traffic Control (ATC) system of the future, a real-time ATC simulation facility has been constructed at NLR. The ATC automation environment of this simulator is provided by CTAS, the Center/TRACON Automation System, developed by the NASA Ames Research Center. For the simulation of air traffic, radar observations, and data link, the NLR ATC Research Simulator (NARSIM) is used. The facility can be used at various levels of automation, ranging from conventional, 'manual' ATC to fully automatic control. For the latter, CTAS has been extended with various decision and control algorithms, dealing with tasks normally executed by the air traffic controller. In a set of real-time simulation experiments different concepts of fully automated ATC are investigated, characterized by various combinations of control functions and different levels of air-ground interaction. Furthermore, the effect of different levels of aircraft navigation performance is studied. The traffic samples are based on single-runway IFR operations for Schiphol Airport, with the traffic mix and distribution based on predictions for the year 2000. The Dutch airspace is simulated with one overall area control sector, controlling traffic from all directions to the three arrival gates, and one Schiphol approach sector, merging the aircraft from these gates into a properly spaced sequence on final approach. For the analysis of the simulations, methods are under development to present overall ATC system performance in terms of safety, flight efficiency, capacity, and control performance. The results of the simulations are used to determine critical areas in ATC system automation, as well as potential benefits thereof. They can also contribute to an optimal distribution of tasks between man and machine in the ATC system of the future. Author (revised)

This paper covers the potential of Decision Making Aids to be implemented before the year 2000 and, within the time frame considered, covers all of the aspects of automated assistance, based on flight path prediction and monitoring, which help air traffic controllers to establish and assess the predicted traffic situation more efficiently. Problem detection, problem minimization, and 'best next clearance' advisories will permit the reduction of the controller's mental workload without decreasing the level of safety or the controller's situational awareness. The central problem of this investigation is the creation of an Air Traffic Control System (ATC) involving both man and machine. The present document reports on two examples which typify the man-machine relationships in systems which are partly automated. In one case, the part played by the machine is detrimental to man's involvement; in the other case, man and machine work together for better results. The manner in which this second approach was used during the development of the CENA's ERATO project is described. Transl. by FLS

Considerations on the design of graphical user interfaces (GUI's) for air traffic controllers are presented in the context of a European Air Traffic Management System (EATMS). The fundamental issues discussed include the following: air traffic controller tasks; human information processing and mental models; and automation strategies with respect to the GUI design. The more specific issues of GUI design which are also discussed include the following: GUI programming environments and standards; development tools; design principles and human factors/human engineering standards; and usability testing. Conclusions are drawn regarding the current background of GUI design with respect to an EATMS and necessary future developments. Author (revised)

Since 1989, the Institute for Flight Guidance of the German Aerospace Research Establishment (DLR) has been developing prototypes of interactive tools in close cooperation with the German Air Navigation Services (DFS) in order to achieve gradual improvements in the efficiency and productivity of the air traffic control system. The paper briefly describes the potential of a selection of analysis and planning tools that have been developed in this framework. After an introduction into the 'planning world' of tactical and strategical air traffic planning, the objectives and potentials of four tools will be demonstrated as applied to real traffic scenarios and actual problems of the current ATM system. Due to increases in air traffic volume and the evolution of operational missions, Alcatel ISR has been awarded a contract to analyze the requirements of military air traffic controllers, especially in the area of the air situation interpretation and the implementation of a mock-up. DAISY is aimed at providing controllers with a decision aid for an air situation interpretation system. In this context, interpretation stands for all the rules and combined information which give an operational meaning to the air situation. Abnormal situations are highlighted, a diagnosis is given, and a proposal is made for decision. After a requirements analysis is conducted, both by experts and controllers during six months, a twelve-month technical feasibility study was led by Alcatel ISR, and a mock-up was developed dealing with typical interpretation scenario such as trajectory prediction. The Institute for Flight Guidance of DLR is involved in medium and long term research and development of concepts, procedures, functions, and components for a future integrated Air Traffic Management System. The medium term work concentrates on improvements concerning the capacity of Frankfurt airport. This paper describes a planned demonstration program which is designed to prove concepts and tools developed by the Institute in cooperation with the German ATC Authority (DFS) and the operator of Frankfurt airport (FAG) as well as with PHARE. The aim of these experiments is to demonstrate the feasibility and merits of integration of onboard avionics with advanced ATC systems on the ground. For this purpose an Air Traffic Management Demonstrator System will be employed, which comprises an air segment and a ground segment connected via an automatic data link and voice communication. The demonstration program will be performed in several phases comprising simulation runs in an air traffic simulator as well as flight tests with a real aircraft. Author (revised)

ADVANCED AIR TRAFFIC CONTROL AND FLIGHT MANAGEMENT SYSTEM CONCEPTS

Robert L. Schultz *In* AGARD, Machine Intelligence in Air Traffic Management Oct. 1993 11 p (For primary document see N94-29558 08-04)

Copyright Avail: CASI HC A03/MF A04

A time-based air traffic control (ATC) system where vehicles are sequenced on desired time of arrival (TOA) has been proposed as one way that might help increase airport capacity. This paper evaluates three time-based ATC system concepts: (1) ground based (computing trajectories on the ground), (2) aircraft based (computing trajectories on the aircraft), and (3) ground and air based (generating parametrized velocity and acceleration profiles on the aircraft and transmitting them to the ground where trajectories are recomputed). The parameters compared are amount of database, complexity of communications, computational requirements, autonomy of aircraft, and similarity to current procedures. The ground-and-air-based approach using parametrized profiles has the best potential for providing a high-landing-rate ATC system with minimal processing and communications requirements. In this approach, ATC assigns time slots at the metering fix based on desired time of arrival (TOA) and range-TOA windows generated on the aircraft. The aircraft sends a simple set of parametrized deceleration and velocity profiles to the ground. The ground processor uses these profiles to generate trajectories and identify conflicts. The ground processor resolves conflicts by examining nearby trajectories using both the sets of parametrized deceleration and velocity profiles and the range-TOA windows. The new horizontal plan and the new profile parameters are sent to the aircraft, where the aircraft flight management system (FMS) regenerates the trajectory and precisely flies it. The advantages of such a system are that it is a natural extension of the current system; it does not require massive ground databases of aircraft thrust, drag and FMS models; it uses a ground processor generating simple models to examine and resolve conflicts; it requires only one air-to-ground interaction; and the aircraft is autonomous. A simulation was used to evaluate the concept. The models used in the simulation are ATC trajectory generator, aircraft FMS, aircraft path controller, and vehicle motion. Multiple-aircraft scenarios, starting in cruise and descent, were examined. Factors examined were separation distances between aircraft on different approach trajectories, accuracy of TOA, and effects of wind-forecast errors on TOA errors.

Rapid technological changes are taking place in the aviation system user facilities - both on the aircraft flight deck and at the aeronautical operational control (AOC), or flight dispatch centers. On the flight deck, the flight management system (FMS) is bringing capability for precise three-dimensional guidance, flight path optimization, and speed control to meet required time-of-arrival (RTA) constraints at key route waypoints. This is enhanced by the precision global navigation satellite system (GNSS), use of digital datalink for communications, and automatic dependent surveillance (ADS). At AOC facilities, advancements in flight planning, flight following, weather information and datalink allow the dispatcher greater flight operations management capability over the airline fleet. This is especially significant for oceanic airspace operations. In parallel, the oceanic air traffic management (ATM) system is undergoing an evolution in automation that will enhance the overall aviation system productivity. Much of the information that each of the three system components - flight deck/FMS, AOC, and ATM - have would be very useful to the other two components for flight efficiency and overall productivity enhancements. Worldwide datalink technology will provide a universal and reliable data communication capability between these components to allow this information sharing. This paper discusses the opportunity to integrate the functions of the FMS, AOC, and ATM computers by exploiting the capabilities of worldwide ground and air data link. First, the outstanding needs of both the oceanic airspace user and traffic management provider are stated. Then, the emerging technological capabilities of ATM automation, FMS and AOC are summarized. This is followed by explicit operational applications where the integration of these capabilities can bring incremental benefits to flight efficiency and human productivity. Needs of both the airspace user and air traffic management service provider are addressed. Operations using today's organized oceanic track system as well as the future free route system are discussed. The opportunities for FMS-AOC-ATM integration are illustrated by three scenarios for oceanic operation. These include a mid-oceanic route replanning task to respond to weather change, a passing maneuver to allow more flexibility in flight speed and altitude when flying along a track system, and use of the FMS RTA capability to meet scheduled track entry gate times with precise accuracy. PROFILE NEGOTIATION: AN AIR/GROUND AUTOMATION INTEGRATION CONCEPT FOR MANAGING ARRIVAL TRAFFIC

David H. Williams, P. Douglas Arbuckle, Steven M. Green, and Wim denBraven *In* AGARD, Machine Intelligence in Air Traffic Management Oct. 1993 11 p (For primary document see N94-29558 08-04)

NASA Ames Research Center and NASA Langley Research Center conducted a joint simulation study to evaluate a profile negotiation process (PNP) between a time-based air traffic control ATC system and an airplane equipped with a four dimensional flight management system (4D FMS). Prototype procedures were developed to support the functional implementation of this process. The PNP was designed to provide an arrival trajectory solution that satisfies the separation requirements of ATC while remaining as close as possible to the airplane's preferred trajectory. The Transport Systems Research Vehicle cockpit simulator was linked in real-time to the Center/TRACON Automation System (CTAS) for the experiment. Approximately 30 hours of simulation testing were conducted over a three week period. Active airline pilot crews and active Center controller teams participated as test subjects. Results from the experiment indicate the potential for successful incorporation of airplane preferred arrival trajectories in the CTAS automation environment. Controllers were able to consistently and effectively negotiate nominally conflict-free trajectories with pilots flying a 4D-FMS-equipped airplane. The negotiated trajectories were substantially closer to the airplane's preference than would have otherwise been possible without the PNP. Airplane fuel savings relative to baseline CTAS were achieved in the test scenarios. The datalink procedures and clearances developed for this experiment, while providing the necessary functionality, were found to be operationally unacceptable to the pilots. Additional pilot control and understanding of the proposed airplane-preferred trajectory and a simplified clearance procedure were cited as necessary for operational implementation of the concept. From the controllers'

perspective, the main concerns were the ability of the 4D airplane to accurately track the negotiated trajectory and the workload required to support the PNP as implemented in this study. Author

The Programme for Harmonisation of ATM Research in Eurocontrol (PHARE) has undertaken to perform the required research work necessary for the introduction of advanced ATM. Within this PHARE framework, it is the task of the PHARE Advanced Tools (PAT's) group to develop the appropriate automation and communication tools to support the air traffic controller. Although the principles for computation, prediction and control of air traffic trajectories are well developed, the various future ATM scenarios reflect different views on the way automation and communication technology can best be applied. The consequence of this is that PHARE research has to be directed towards multiple ATM scenarios, and that the PAT's to be developed should be applicable to automation and communication under different ATM scenarios. The paper gives an overview of the approach taken by the PAT's group in facing this challenge. Author

THE COMMON MODULAR SIMULATOR (CMS): AN ARCHITECTURE TEST BED FOR FUTURE ADVANCED ATM SYSTEMS
J. R. Velten *In* AGARD, Machine Intelligence in Air Traffic Management Oct. 1993 8 p (For primary document see N94-29558 08-04)
Copyright Avail: CASI HC A02/MF A04

The Common Modular Simulator (CMS) project is part of the Program for Harmonized ATM Research in Eurocontrol (PHARE). The main objective of this project is to provide a common integration environment which shall allow the creation of a homogeneous infrastructure in order to facilitate and harmonize the development as well as the evolution of ATM simulators in the different research establishments. To meet such an ambitious objective, CMS partners have adopted a system architecture based on a client-server model with active servers providing event subscription and event notification mechanisms. The main advantages of such client-server models are to offer a very modular system architecture and to provide, through the associated application programming interface (API), a very powerful mechanism of abstraction. This leads to a very flexible, evolutive, open, scalable and adaptable system. CMS will offer an architecture test bed for future advanced ATM systems. As a consequence, this project should be of great benefit to many other ATM projects. Author (revised)

The 'Studies, Tests, and Applied Research' (STAR) program of the EUROCONTROL Agency is addressing several implementation timescales for air traffic management (ATM) systems and procedures. ARC2000 (automatic radar control 2000) is presently the major long-term component of the STAR program, for implementation beyond 2015. ARC2000 is addressing the enroute ATC capacity issue, which is severe in Europe, by investigating the limit case where both major constraints, workload and sectorization, are eliminated. It is often easier to solve a complex problem by first looking at the limit case. ARC2000 could not be implemented as such, but should provide precious information with respect to feasible levels of automation in the long term. There are also significant by-products which will speed up shorter term research. Indeed, ARC2000 provides a 20-30 minute conflict-free planning which is a key feature of the European Air Traffic Management System (EATMS) concept. Author (revised)

Modern high precision navigation systems based on satellite and inertial navigation provide a positioning accuracy that has never been achieved before, for aircraft enroute as well as during approach and on the airfield. By using such combined accurate positioning systems it is possible to guide aircraft on the ground and to perform automatic taxiing, which further increases the safety of ground operations. Whenever high precision terrestrial navigation is needed, common aeronautical navigation displays are not able to provide the information, which easily can be combined with the pilot's view from the cockpit, to deliver the necessary guidance aid. A flexible map display is desired to be shown in the cockpit. The new taxi guidance system GINaS, presented in this paper, is based on an integrated navigation system (DGPS/INS) and a digital map using only the standard display and navigation hardware of modern commercial aircraft. The system was successfully tested in one of our testbeds, a van. This van can be driven automatically by the system as well as by the pilot using the information of the digital map and a drive-director. The accuracy reaches submeter level. Author (revised)

In the modern world there is an increasing need for surveillance, and a consequent need for automatic or semi-automatic methods for processing dynamic input data and presenting it in a form which is useful to the end user. This paper outlines advanced knowledge-based techniques for monitoring such data. The techniques have been applied to airport ground traffic applications and demonstrated in particular on data from actual turn-round scenarios for stand area servicing of an aircraft as observed by a single camera. Results are output in real-time as a status report by an integrated system which is designed to handle the vagaries of real data in respect to incompleteness and uncertainty. The new techniques developed can also be applied to other ground movements surveillance applications which have multiple sensor inputs of the same or different modalities.

A NOVEL NEAR-RANGE RADAR NETWORK FOR AIRPORT SURFACE CONTROL

K.-H. Bethke, B. Roede, M. Schneider, and A. Schroth *In* AGARD, Machine Intelligence in Air Traffic Management Oct. 1993 14 p (For primary document see N94-29558 08-04)

Copyright Avail: CASI HC A03/MF A04

This contribution describes a radar network for airport surface movement guidance and control. The network comprises several low power radar stations which are organized in modules of four stations each. All antennas are staring and illuminating the area continuously. Moving objects are localized by range profile measurements and a subsequent multilateration. Each module runs autonomously. The module computer at the master station calculates the multilaterations and controls the communication with three slave stations. The measured data from these stations are transferred via the radar transmitters to the master station, while the multilateration and imaging results are sent via data cables to the central computer. There, the information from all modules will be merged and tracks will be constructed; furthermore, a classification process on the basis of the images will be executed. Author (revised)

This paper describes the results of a research program to investigate the use of advanced radar, display systems, and controller alert automation aid to increase capacity at airports with closely spaced parallel runways. Analysis has indicated that the runway spacing could be reduced without adversely affecting capacity if a surveillance radar of higher update and accuracy and a high resolution color display system with controller alert automation aid are used. This paper first describes a research program to demonstrate the feasibility of using a precision runway monitor (PRM) system for conducting independent simultaneous approaches to parallel runways spaced at less than 3400 ft (1035 m) apart. A PRM system consists of an improved radar system that provides high azimuth and range accuracy and higher data rates than the current terminal airport surveillance radar (ASR), a processing system that monitors all approaches and generates controller alerts when an aircraft appears to be blundering, and a high resolution color display. Two airports were selected to serve as the demonstration and test facilities of the PRM system. This paper describes the key elements of the demonstration program including test criteria and scenarios, controller and pilot/aircraft response times, and risk analysis. Results of the demonstration program on the feasibility of the 3400 ft runway spacing standards using PRM are presented. Recommendations on radar update rate, accuracy, and display requirements for the PRM system are summarized. This paper also describes the follow-on research activities to investigate further reduction of parallel runway spacing standards to below 3400 ft using the PRM system and advanced navigation and landing systems. Applications and extension of research results to triple and quadruple closely spaced parallel runways are discussed.

A GUIDANCE AND NAVIGATION SYSTEM FOR TWO SPACECRAFT RENDEZVOUS IN TRANSLUNAR HALO ORBIT Ph.D. Thesis

Brian Leigh Jones 1993 203 p

Avail: Univ. Microfilms Order No. DA9323444

This research considers the design of a representative end-to-end guidance and navigation system for the terminal phase rendezvous of two spacecraft in the circular restricted three-body problem. It assumes the target vehicle is in a small radius translunar halo orbit; the target vehicle remains passive with respect to the rendezvous profile. The chaser vehicle is in an independent small radius translunar halo orbit and executes all rendezvous maneuvers. First, the halo orbit guidance problem is formulated in the frequency-domain from which an output feedback guidance law is developed using H(sub 2) control theory. Linear simulation results validate the guidance law and provide data which quantify the effect of control inputs, noise characteristics and halo orbit characteristics on the steady state halo orbit station-keeping costs. Secondly, a two space-craft terminal phase rendezvous targeting law is derived; nonlinear simulation results validate the targeting law. Using these results, the three-body terminal phase rendezvous problem is further characterized and contrasted with the two-body problem. Thirdly, a rendezvous navigation filter is constructed to supply the targeting law with chaser vehicle state information. Nonlinear simulation results validate the filter design and provide data to assess the filter performance. Lastly, two rendezvous scenarios are examined to demonstrate the complete system design. EXTREMELY LOW VISIBILITY IFR ROTORCRAFT APPROACH (ELVIRA) OPERATIONAL CONCEPT DEVELOPMENT. VOLUME 1: EXECUTIVE SUMMARY Final Report

Catherine A. Adams, Richard J. Adams, Scott A. Fontaine, and Howard A. Wheeler Mar. 1994 51 p

(Contract DTFA01-89-C-00016)

(DOT/FAA/RD-94/1,I) Avail: CASI HC A04/MF A01

The Extremely Low Visibility IFR Rotorcraft Approach (ELVIRA) workshop was the second since 1987 to address the enhancement of safety and reliability of helicopter operations by improving the attractiveness of IFR operations in lieu of special VFR operations. The 1993 workshop was the next logical step in the FAA's Vertical Flight research and development program since significant, relevant analyses, simulation and flight test work has been accomplished in the past six years. The workshop was held in Santa Fe, New Mexico on August 24-26, 1993. The participants were a select group of 59 industry and government experts in each of their individual disciplines. The group was charged with the task of defining an ELVIRA operational concept in the areas of: operational needs, infrastructure requirements, procedural changes, technology requirements, night tests, and public benefits. These experts were asked explicitly to address affordable and practical near term solutions to issues previously identified through their experience. The deliberations at the workshop resulted in the identification near term needs of the operator types who would use ELVIRA, activity regions, safety factors and operational improvements. These needs were analyzed and the operational changes responsive to the needs were documented. The proceedings of the workshop culminated with a recommendation of ten IFR enhancements that would eliminate current penalties for using the IFR system. If action is taken to achieve these changes, safety and mission reliability will be increased through increased flight hours under positive control. Volume 1 summarizes the activities and contributions of the participants. Volume 2 provides an overview of the presentations at the workshop. Volume 3 documents the perspectives of the participants as recorded by Technical Monitors and observers. Author

TOWARDS 10(EXP 9) GPS GEODESY: VECTOR BASELINES, EARTH ROTATION AND REFERENCE FRAMES Annual Progress Report, 1 Jan. 1993 - 31 Dec. 1993

Bob E. Schutz 10 Mar. 1994 25 p

(Grant NAG5-1936)

(NASA-CR-195768; NAS 1.26:195768) Avail: CASI HC A03/MF A01

Effort during the period form January 1, 1993 to December 31, 1993 were in the following areas: GPS orbit accuracy assessments and efforts to improve the accuracy; analysis and effects of GPS receiver antenna phase center variation; analysis of global GPS data being collected for the IGS campaign; and analysis of regional (south west Pacific) campaign data. A brief summary of each of the above activities is presented.

A SIMULATOR FOR MULTI-RADAR ANALYSIS FOR REALISTIC TRAFFIC

R. A. Hogendoorn, F. Heerema, and P. Sauer 12 Jan. 1992 19 p Presented at the Workshop on RASS, Eurocontrol Institute, Luxembourg, 14-16 Dec. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B179099; NLR-TP-92481-U; ETN-94-95964) Avail: CASI HC A03

An overview of the SMART (Simulator for Multiradar Analysis for Realistic Traffic) radar simulator is given. A generic simulator model is presented

and the two major subsystems of SMART, the Traffic Subsystem (TSS) and the Radar Subsystem (RSS) are described. Software engineering aspects are discussed and samples of test results are presented in order to show the simulator operation. ESA

A STOCHASTIC CONTROL APPROACH TO FLIGHT PATH MONITORING

B. A. vanDoorn and H. A. P. Blom 31 Jan. 1992 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B174630; NLR-TP-92020-U; ETN-94-95570) Avail: Issuing Activity (European Space Agency (ESA))

A stochastic control approach used to obtain an idea of the qualitative aspects of flight path monitoring is described and first results achieved with it are reported. Two kinds of stochastic control are dealt with: stochastic impulse control and stochastic continuous control. For the latter one, a LQG problem formulation (a Linear model under Gaussian noise with a Quadratic cost function) is considered. For this type of problem formulation, the optimal control is known. A number of experiments are executed to illustrate the optimal control for a simple flight path monitoring problem. The results of these experiments, in combination with the analytical results from impulse control theory, provide a sound basis for the design of a flight path monitoring tool. ESA

A REVIEW OF THE STATUS AND CAPABILITIES OF NAVSTAR GPS

N. vanDriel 10 Feb. 1992 12 p Presented at the Netherlands Institute of Navigation Navstar Global Positioning System Workshop, Amsterdam, Netherlands, 27 Sep. 1991 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B174629; PB94-126281; NLR-TP-92042-U; ETN-94-95571) Avail: CASI HC A03

A general description of the Navstar Global Positioning System (GPS) is given. A technical description of the space segment, control segment, and user segment is also given. The program history and present status are recalled. The system performance is evaluated considering the levels of service, precise positioning service, and standard positioning service. Implications related to the possible use of GPS as an operational navigation system are discussed. In order for the system to be used as an operational navigation system for mariners or aviators, it is required that certain criteria for availability, accuracy and integrity are met. Some evolving new techniques are discussed: differential GPS, dynamic carrier tracking, and attitude determination. ESA

Simulator testing, conducted to collect and analyze crew performance and crew response in order to address several issues on equipment failures, is reported. The testing provided both quantitative measures such as aircraft positional errors, aircraft state and control parameters, and qualitative data such as responses to pilot questionnaires and pilot comments. The specific objectives of the present tests are: to expose crews, while flying a moving base flight simulator programmed with the flying qualities of a wide body transport aircraft, to Microwave Landing Systems (MLS) based curved path approach and departure procedures which have been found to be beneficial from an air traffic control point of view; to collect pilot perception and performance data while flying these curved path procedures; to measure crew ability to detect insidious failures and to respond to these failures; to measure crew performance and to collect perception data when the crew must revert to basic MLS position awareness data in the presence of a navigation or guidance failure; to evaluate performance on a complex approach path with one (critical) engine inoperative. MAINTAINING VIGILANCE ON A SIMULATED ATC MONITORING TASK ACROSS REPEATED SESSIONS Final Report

D. J. Schroeder, R. M. Touchstone, J. A.. Stern, N. Stoliarov, and R. Thackray Mar. 1994 13 p Prepared in cooperation with Massachusetts Inst. of Tech., Cambridge

(Contract DTFA02-90-R-00149)

(DOT/FAA/AM-94/6) Avail: CASI HC A03/MF A01

Maintaining alertness to information provided visually is an important aspect of air traffic controllers' work. Improper or incomplete scanning and monitoring behavior is often referred to as one of the causal factors associated with operational errors and deviations. This study was undertaken to assess changes in vigilance/attention across 3 separate days as subjects performed on an Air Traffic Control (ATC) simulation task. Information was gathered as part of a larger study of attention and 'gaze control inefficiencies.' Twenty paid subjects on 3 separate days monitored a simulated ATC task for 44 critical events over a 2 hour session. The complex monitoring task included the detection of: (1) altitude malfunctions; (2) aircraft conflict/no conflicts where 2 aircraft were at the same altitude on an airway simultaneously; and (3) triangular targets representing VFR aircraft that appeared either centrally or peripherally on the screen during the course of each session. Changes in performance on the complex monitoring task associated with either time-on-task or repeated sessions were dependent on nature of the task. Performance on the component involving detection and decision-making (conflict/no conflict detection) evidenced a decrement associated with time-on-task on each of the 3 days. Improvement was evident from the first to the third day. Performance on the identification of the altitude malfunctions remained relatively immune to the effects of time-on-task or repeated sessions. Detection of the VFR aircraft intruders presented a mixed picture, with improvement noted in some aspects of performance but not in others, and some evidence of time-on-task effects. Outcomes were generally consistent with previous findings with this task and consistent with other literature with respect to the presence of performance decrements associated with time-on-task. The results were consistent with a view that the decrements are associated with lapses in attention or 'blocks,' rather than a generalized fatigue effect or a general modification in overall scanning behavior. Furthermore, the results suggest that there were aspects of monitoring performance that remain relatively immune to time-on-task effects, even during the course of the three 2-hour sessions. Author

THE EXPERIMENTAL FLIGHT MANAGEMENT SYSTEM: AN AIR TRAFFIC MANAGEMENT RESEARCH TOOL

Job Brueggen 29 Jun. 1992 14 p Presented at the 1992 SFTE Annual Symposium on Flight Testing in the Global Environment, Long Island, NY, 3-7 Aug. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(NLR-TP-92253-U; ETN-94-95972) Avail: CASI HC A03

The Experimental Flight Management System (EFMS) program, part of a European collaborative research program called PHARE (Program for Harmonized ATM (Air Traffic Management) Research in Eurocontrol), which aims to investigate a future ATM scenario, is described. The EFMS will incorporate some revolutionary features, of which the most important are to plan and fly a four dimensional trajectory and to negotiate that trajectory via a digital data link with air traffic control. Development is a multinational activity of the aerospace centers of Germany, France, England and the Netherlands, coordinated by Eurocontrol. A first demonstration is planned for Jan. 1993. A number of applications of the EFMS program are described, most notably the avionic research test bed. ESA

EFFECTS OF REPAIR ON STRUCTURAL INTEGRITY Final Report, Jan. 1990 - Sep. 1992
R. Rice, R. Francini, S. Rahman, M. Rosenfeld, S. Rust, S. Smith, and D. Broek Dec. 1993 156 p
(Contract DTRS57-89-C-00006)
(AD-A275756; DOT-VNTSC-FAA-93-11; DOT/FAA/CT-93/79) Avail: CASI HC A08/MF A02

FAA regulations require commercial aircraft operators to repair damaged aircraft structures. These repairs must be performed in a timely manner to reduce aircraft downtime and loss of revenue. A guiding principal for such repairs is to restore the structure to the original (or better) static strength and stiffness. However, the repair can also be designed for adequate fatigue resistance, damage tolerance, and inspectability. Fatigue and damage tolerance (DT) analyses should be based on realistic stress histories which, in turn, should be derived from realistic load spectra. Thus, an algorithm for the development of a stress history should be included in a comprehensive analysis of repairs. Since many damage repair stations and airlines do have at least basic computer facilities that can be used for fatigue and damage tolerance analysis, one goal has been the development of a relatively simple, yet accurate analytical tool to design aircraft repairs more effectively. The structural analysis and stress spectrum development procedures described in this report are approximate and, therefore, have certain limitations. These procedures might be used to qualitatively compare the quality of different repair options with the original structure. DTIC

FULL-SCALE TESTING AND ANALYSIS OF CURVED AIRCRAFT FUSELAGE PANELS Final Report, May 1991 - Mar. 1992
G. Samavedam, D. Hoadley, and D. Thomson Dec. 1993 58 p
(Contract DTRS57-89-D-00009)
(AD-A275666; DOT-VNTSC-FAA-93-10; DOT/FAA/CT-93/78) Avail: CASI HC A04/MF A01

This report presents data on (1) residual strength of aircraft panels containing Multiple-Site Damage (MSD) in tap splices, and (2) fatigue strength of panels subjected to cyclic pressure loading. The testing was conducted using the dedicated Aging Aircraft Test Facility previously built in the Foster-Miller laboratory. A previous report describes the work in the first phase involving the design and operation of the facility and the test data generated on residual strength of panels with longitudinal midday skin cracks. In the Phase II work presented here, several residual strength tests were conducted to develop a relationship between failure pressure and the lead crack length in the critical upper rivet line of the lap joint. In some of the panels multiple-site damage was also built in the rivet line during fabrication. The reduction in the residual strength due to MSD has been experimentally quantified. Conditions of crack arrest at tear straps and panel flapping were also investigated. Fatigue testing of the panel, with no initial damage in the tap splice except an unbonded lap joint area, was conducted to investigate the crack initiation at multiple sites, crack growth rates and eventual linkup of the ligaments and fracture failure. The ultimate life of the panel, and the damage in critical upper and lower skin rivet rows was determined. Conclusions of practical interest were drawn from the test data. DTIC

A MOMENT PLOTTING METHOD FOR CHARACTERIZING AIRCRAFT FATIGUE DATA POPULATION DISTRIBUTIONS M.S. Thesis
Rolf M. Lokensgard Sep. 1993 106 p
(AD-A275500) Avail: CASI HC A06/MF A02

A method was developed where, by statistically analyzing samples of aircraft fatigue data from a population, the population's probability distribution function is determined. The method uses plots of a sample's coefficient of variation, and measures of skewness and kurtosis, superimposed on templates of curves created from the moment functions of normal, lognormal, Weibull, and exponential distributions. The moment functions are derived for each distribution. The plotting technique is combined with a comparison of goodness of fit statistics to form the complete distribution selection method. The method is first tested on random numbers generated from known distributions to see if the correct distributions are selected; then the method is applied to helicopter loads data, fatigue life characterization test data, and counting accelerometer data. (Contract NCC2-834)
(NASA-CR-195737; NAS 1.26:195737) Avail: CASI HC A03/MF A01

This paper presents the development of a computer simulation of agility flight test techniques. Its purpose is to evaluate the agility of aircraft

configurations early in the preliminary design phase. The simulation module is integrated into the NASA Ames aircraft synthesis design code. Trade studies using the agility module embedded within the design code to simulate the combat cycle time agility metric are illustrated using a Northrop F-20 aircraft model. Results show that the agility module is effective in analyzing the influence of common parameters such as thrust-to-weight ratio and wing loading on agility criteria. The module can also compare the agility potential between different configurations and has the capability to optimize agility performance early in the design process. Author

ACQUISITION, DESIGN MODIFICATION, ASSEMBLY, AND GROUND TEST OF NPS HUMMINGBIRD REMOTELY PILOTED HELICOPTER M.S. Thesis
Gregory J. Fick Sep. 1993 93 p
(AD-A275546) Avail: CASI HC A05/MF A01

The Hummingbird is a 150-lb. gross weight, remotely piloted helicopter (RPH) with a 50-lb. payload and a rotor radius of 10.25 ft. It is powered by a 25 h.p. air cooled two-cylinder Westlake engine. As such it represents one of the largest RPH's in the world. It was purchased from Gorham Model Products in 1992 to provide a suitable rotorcraft research flight test platform for the Department of Aeronautics and Astronautics at the Naval Postgraduate School. The helicopter was delivered disassembled and was accompanied by an ample supply of replacement and spare parts. Also included was a second helicopter in a partially assembled condition that had been previously flown. Assemblies provided comprised the chassis, main rotor transmission, rotor head assembly, and tailboom with tail rotor gear box and rotor. The task undertaken by this thesis was to fabricate one operable RPH and to design, fabricate, and install whatever new assemblies that were required for its NPS mission and to make up for deficiencies in the previous design. The work completed required: (1) design, fabrication, and installation of a new skid-type landing gear system; (2) redesign and incorporation of a new engine mount system; (3) modification of the engine and main rotor transmission coupling; (4) upgrade of the electrical system and elongation of the nose section; and (5) initial engine testing. Recommendations for future modifications to the helicopter and laboratory facilities and development of a static hover test fixture are also included. DTIC

N94-28870# Naval Postgraduate School, Monterey, CA.
PROCEDURAL GUIDE FOR MODELLING AND ANALYZING THE FLIGHT CHARACTERISTICS OF A HELICOPTER DESIGN USING FLIGHTLAB M.S. Thesis
Gary P. McVaney 23 Sep. 1993 150 p
(AD-A275077) Avail: CASI HC A07/MF A02

This thesis presents one method for modeling and analyzing a helicopter design using Flightlab. Flightlab is a computer program that provides for engineering design, analysis, and simulation of aircraft using nonlinear dynamic modeling techniques. The procedure to model a single main rotor helicopter is outlined using a sample helicopter design. The analysis procedure contains computer program scripts for determining the time response of the helicopter to standard control inputs such as a longitudinal impulse, a lateral step, and a pedal doublet. A linear model of the helicopter can be extracted from the nonlinear model, and a comparison of the time response to the control inputs based on these two models is presented. The procedure for conducting frequency sweep testing for the linear model is also discussed. This guide to using Flightlab for aircraft modelling and analysis is designed to make it easier to use Flightlab for creating additional aircraft models for use in control system analysis and additional engineering design. EXPLORING QDES AS A TOOL FOR DETERMINING LIMITS OF ACHIEVABLE PERFORMANCE IN AIRCRAFT DESIGN M.S. Thesis
Mark F. Reidinger Dec. 1993 151 p
(AD-A275359; AFIT/GAE/ENY/93D-23) Avail: CASI HC A08/MF A02

This thesis explores the usefulness of a computer aided control design software package called QDES in determining the limits of achievable aircraft performance as it relates to controller capability. Modern aircraft, particularly fighters, are being designed to be statically unstable to enhance their maneuverability and performance. It is possible that the aircraft, although physically capable of a certain level of performance due to its engine/airframe combination, may be uncontrollable up to this level. This study sought to develop a methodology to use QDES to make a preliminary analysis of an aircraft design to determine if there exists a controller that will enable this design to meet its performance goals and, if not, to determine what the limits of achievable performance are. BACKSCATTER HAZE DEVICE FOR MEASUREMENT OF HAZE IN AIRCRAFT TRANSPARENCIES Final Report, Jan. 1991 - Dec. 1992
H. L. Task (Air Force Systems Command, Wright-Patterson AFB, OH.), Richard J. Bartell, and Sheldon E. Unger May 1993 36 p
(AF Proj. 7184)
(AD-A275127; AL/CF-TR-1993-0102) Avail: CASI HC A03/MF A01

The method currently used throughout the aircraft transparency industry to measure haze is ASTM Test Method D1003. This procedure was originally developed for applications involving small, thin, and flat transparent parts. Major limitations of Test Method D1003 include its restriction to small, flat samples and its requirement for having the source and detector on opposite sides of the sample under test. In order to facilitate field testing of installed aircraft windscreens, a test method was developed which overcomes the limitations of Test Method D1003. The new method determines haze values by measuring the amount of light backscattered off the surface of the transparency under test. A prototype instrument was developed and tested against D1003. The results of those tests are presented. The new instrument consists of an integrating sphere, a mechanically chopped incandescent light source, a silicon detector, and supporting electronics. This report describes the device, which is based on U.S. Patent Number 4,687,338, in detail. Use of this type of device in the field could provide quantitative data for determining when an installed aircraft windscreen should be replaced or refinished in place. DTIC

A NON-LINEAR SIMULATION FOR AN AUTONOMOUS UNMANNED AIR VEHICLE M.S. Thesis
David R. Kuechenmeister Sep. 1993 123 p
(AD-A275062) Avail: CASI HC A06/MF A02

Unmanned Air Vehicles have become increasingly important on the modern battlefield. The restrictive requirement for runways and special equipment to take off and land was partially solved by the vertical take off and landing Airborne Remotely Operated Device, AROD. Work done at the Naval Postgraduate School has modified the AROD to not only land and launch vertically, but to fly horizontally for the majority of the mission. To realize these capabilities, as well as that of autonomous flight, an accurate computer model was required of both the AROD and the avionics test bed aircraft, Bluebird, in order to design the control and navigation systems. High fidelity, non-linear equations of motion were derived in matrix form that represented any six degree of freedom aircraft model, and they were then tailored for use on specific aircraft. Computer modeling of the resulting equations of motion, as well as the sensors used on the aircraft, was done using SIMULINK and MATLAB software. The resulting computer model provides a non-linear system of equations, which are easily linearized at any desired flight condition, as required by the proposed control and navigation system design. KC-135 COCKPIT MODERNIZATION STUDY AND CREW REDUCTION FEASIBILITY DEMONSTRATION Final Report, 15 Aug. 1992 - 31 Aug. 1993
John E. Ehrhart, Jr., Jordan R. Kriss, Janet M. Emerson, and Thomas C. Hughes Oct. 1993 123 p
(AD-A275230; ASC-TR-93-5023) Avail: CASI HC A06/MF A02

Future KC-135 missions will require significant increases in aircraft flexibility to respond to the Air Force vision of Global Reach, Global Power. Such flexibility typically translates into advanced avionics systems and system capabilities; however, a large percentage of the avionics systems currently installed on the KC-135 are late 1950's and 1960's technology which has degraded the efficiency, reliability, maintainability and safety of the KC-135 mission. Strategic Air Command (SAC), now Air Mobility Command (AMC) issued a statement of need (SON, 1987) addressing the need to modernize the KC-135 cockpit avionics to attend to these problems. This report documents the evaluation phase of this program and for the first time

directly compares the two-man and three-man cockpit configurations. The validation of the reduced crew consisted of a comparison of crew performance across three distinct missions - Minot, Castle and Desert. Results supported the two-person (No Nav) cockpit, given certain modifications. Based on these results, the CSEF recommended follow-on flight test of the KC-135. Recommendations are based upon using the final design, identical in system capabilities, as developed at the Crew Station Evaluation Facility. The key to the success of this program lies in the utilization of the modifications discussed in this report and the proper implementation of those modifications in future KC-135 cockpits. DTIC

HELICOPTER MISSION AND ROTOR PERFORMANCE OPTIMIZATION WITH QUASI-LINEAR INFLOW THEORY Ph.D. Thesis
Azhar Mansur Khan 1992 149 p
Avail: Univ. Microfilms Order No. DA9315887

The enhanced performance envelope of a future generation rotorcraft is greatly desired by all the designers. This design goal can be achieved through rotor performance optimization design methodology, which in simple words is a numerical technique for obtaining the design goals by satisfying the design requirements. The design goal for rotorcraft performance optimization is the reduction of rotor power for a specific weight and mission while the design variables are the rotor chord and twist which define the rotor blade geometry. Constraints are applied to satisfy certain minimum design requirements. Since optimization is a complex numerical iterative procedure, which utilizes a considerable amount of computation time, it is desired by all designers to come up with such an aerodynamic model for helicopter performance calculations which utilizes minimum amount of computer processing time. In view of the above, a steady non-uniform inflow model is used to calculate the rotor performance for both hover and forward flight. The main emphasis of this research work has been to simplify the inflow model without loss of accuracy since, ultimately, this research work is going to be a part of the multidisciplinary helicopter design optimization. Therefore, all time dependent terms have been neglected and all pressure functions and power expressions have been time averaged. After neglecting unsteady terms it was required to take care of the blade tip loss; for which the Prandtl's tip loss function has been used. All complex integrals have also been calculated ahead of time and stored in data files to be used as input to the main program as and when required. The rotor performance code is then modified to a nonlinear constrained optimization problem to be used as input to the optimization routine. The updated version of a FORTRAN routine (CONMIN) for constrained function minimization is used for optimization purpose. Finally, the most optimum planform for the rotor is obtained from the point of view of taper and twist, that requires the least amount of power for a given thrust for hover, for forward flight, and for certain specified missions. The missions to be optimized are a combination of both hover and forward flight. Thus, this research work is an analytical formulation of an optimum rotor for various pre-defined missions. Dissert. Abstr.

AIRCRAFT SYSTEM AFT TELESCOPE CAVITY CONFIGURATION STUDY FOR STRATOSPHERIC OBSERVATORY FOR INFRARED ASTRONOMY (SOFIA), PHASE 2 Final Report
22 Apr. 1994 171 p Original contains color illustrations
(Contract NAS2-13872)
(NASA-CR-194266; NAS 1.26:194266; R54045007) Avail: CASI HC A08; 62 functional color pages color pages

The SOFIA Aircraft System (AS) Phase 1 Study was a broad-based study which addressed itself to satisfying technical and programmatic requirements by drawing from existing technology and applying cost-efficient commercial approaches to the aircraft modification. In this SOFIA AS Phase 2 Study, five critical areas of the aircraft were selected for more detailed investigation: forward pressure bulkhead, aft bulkhead, 'free' shell to bulkhead interface, shell cut-out to bulkhead interface, and flooring. The in-depth investigation of these areas upon a finite element model (FEM), with a fine grid model in areas of particular interest, is discussed. The FEM code used is called 'STRAP' and was developed by the engineering firm, Rasmussen and Associates. STRAP is NASTRAN compatible to within 1%. The loads applied to the model were approximated from known 747 envelope conditions. The areas of investigation, and a section through the fuselage is shown. The thrust of this investigation was to develop the design concepts conceived under phase 1 to the point where detailed design could be undertaken with a high level of confidence.

The work conducted by the ELORET Institute under this Cooperative Agreement includes the modeling of hypersonic propulsion systems and the evaluation of hypersonic vehicles in general and most recently hypersonic waverider vehicles. This work in hypersonics was applied to the design of a two-stage to orbit launch vehicle which was included in the NASA Access to Space Project. Additional research regarded the Oblique All-Wing (OAW) Project at NASA ARC and included detailed configuration studies of OAW transport aircraft. Finally, work on the modeling of subsonic and supersonic turbofan engines was conducted under this research program.

INTEGRATED PROPULSION-AIRFRAME DYNAMICS AND CONTROL Ph.D. Thesis
Ronald A. Perez 1990 329 p
Avail: Univ. Microfilms Order No. DA9313941

The development of an integrated control scheme to enhance the performance of a generic interconnected multivariable dynamical system, consisting of a turbofan engine and an airframe, in the presence of predominantly destructive dynamical interactions over the flight envelope is considered in this research. The control scheme consists of two components: a simple static forward loop or feedback loop precompensator to improve the interactions followed by a forward or feedback loop controller to improve the performance. System performance specifications dictate zero steady state errors in the engine and airframe controlled output variables as well as minimal overshoot with rapid and smooth acceleration and deceleration profiles. Furthermore the system must be tolerant to soft and hard output sensor failures by means of analytic redundancy only. A control methodology to satisfy the above specifications is presented here. Necessary and sufficient conditions are presented in order to achieve stable closed loop performance of the overall system by tuning every loop separately (i.e., decentralized stability). This leads to very simple control structures, but even for these rather simple control schemes, a significant improvement over previous integration schemes is obtained. Dissert. Abstr.

ROTORCRAFT AIRFRAME STRUCTURAL OPTIMIZATION FOR VIBRATION AND DYNAMIC STRESS REDUCTION INCLUDING DAMPING TREATMENT Ph.D. Thesis
Ashish Kumar Sareen 1992 129 p
Avail: Univ. Microfilms Order No. DA9315910

This work focuses on the development of finite element based methodologies for mass, stiffness, and damping modifications of practical airframe structures. This preliminary design type of engineering methodology of analysis and optimization allows rapid and accurate engineering prediction and placement of responses while guiding the structural designer-dynamicist in determining the location, type and quantity of structural modifications when the airframe is sustaining severe forced vibrations. For new airframe structures, minimum weight structures can be designed with proper placement of airframe natural frequencies and subject to constraints on forced response displacements and dynamic stresses by systematic nonlinear programming-based modifications of mass, stiffness and damping of the structure. In the case of an existing design, when significant mass and stiffness modifications cannot be affected, the designer can resort to viscoelastic type energy-dissipation damping treatments and determine their efficacy. Furthermore, should the change of excitation frequency bring about modal resonance, damping treatments can control response due to resonating modes, without resorting to stiffness or mass changes. This work focuses on the development of necessary computational tools for airframe structural optimization and implements the sensitivity analysis procedures for the various design constraints encountered in vibration and fatigue design of structures. The application of the optimization procedure

is demonstrated using both an elastic-line as well as a built-up finite element model of the Bell AH-1G helicopter airframe structure.

AIRCRAFT EVACUATIONS: THE EFFECT OF A CABIN WATER SPRAY SYSTEM UPON EVACUATION RATES AND BEHAVIOUR

D. M. Bottomley (Cranfield Inst. of Tech., Bedford, England.), H. C. Muir (Cranfield Inst. of Tech., Bedford, England.), and M. C. Lower (Southampton Univ., England.) Mar. 1993 71 p Original contains color illustrations

(CAA-Paper-93008; ISBN-0-86039-547-2; ETN-94-95514) Copyright Avail: Issuing Activity (Civil Aviation Authority, Greville House, 37 Gratton Road, Cheltenham, England, HC)

An experiment which investigated the human factors aspects of water spray systems, proposed as a means of reducing the effects of fire occurring in an aircraft cabin, is reported. The potential effects of such systems upon evacuation rates and other issues such as visibility and audibility within the cabin were investigated. In total, eight full scale aircraft evacuations were conducted using a 707 airframe. Each evacuation involved a group of around forty five adults who performed one evacuation only. Four groups evacuated in dry conditions, the remaining four evacuated in the water spray. Video cameras were positioned both inside the aircraft cabin and on the platform outside to provide objective measures of evacuation performance. Subjective accounts were also obtained using post evacuation questionnaires. The results revealed that the evacuation times for the two conditions were virtually identical, the lack of a statistically significant difference suggesting that the presence of the water spray did not affect evacuation rates. Other results are given. ESA

ACOUSTIC EMISSION MONITORING OF AGING AIRCRAFT STRUCTURES

S. L. McBride, M. R. Viner, and M. D. Pollard Mar. 1993 13 p

(DREP-93-17; CTN-94-61135) Avail: CASI HC A03/MF A01

Acoustic emission measurements were used to detect fatigue cracks in a full-scale aircraft structure during ground durability and damage tolerance testing. Measurements were made using a 16-channel data acquisition system receiving signals from piezoelectric sensor elements. Fatigue cycling loads were applied at various loading points on the aircraft structure to simulate the known flight load spectra measured in flight. Acoustic emission data were recorded for 700 equivalent flying hours and analyzed at intervals. After 700 hours of testing it was clear from the acoustic emission data that significant crack growth was occurring in the starboard wing skin. Fasteners were removed to inspect fastener holes in the damage area identified by acoustic emission. Fatigue cracks were detected in several holes using eddy current only after the structure was loaded to open the cracks. Acoustic emission data were further analyzed to reconstruct the history of defect growth and to separate the crack growth emission data from crack face rubbing data. The tests show that cracks originating inside fastener holes can be detected easily by acoustic emission without the removal of fasteners. Acoustic emission monitoring is shown to be superior to conventional nondestructive testing in locating fatigue cracks and can be used to determine load conditions leading to crack growth.

ENHANCED FATIGUE CRACK DETECTION IN AGING AIRCRAFT USING CONTINUOUS ACOUSTIC EMISSION MONITORING

Stuart L. McBride, Yanhua Hong, and Michael Pollard Feb. 1993 12 p

(DREP-93-16; CTN-94-61137) Avail: CASI HC A03/MF A01

Acoustic emission measurements were used to detect fatigue cracks in a full-scale aircraft structure during ground durability and damage tolerance testing. Data are presented for about 3,000 equivalent flying hours of continuous monitoring. Acoustic emission data were acquired via piezoelectric sensors using a 32-channel instrumentation system. The regions of the aircraft structure monitored were located on the lower wing skin, particularly the 15 percent, 39 percent, and 44 percent spar regions. Fatigue cycling loads were applied at various loading points to simulate the known flight load spectra measured on flying aircraft. Defects detected by acoustic emission and confirmed by conventional nondestructive methods were of two types: fatigue cracks in fastener holes repaired at or before 9,754 equivalent flying hours or new defects occurring principally at the wing skin edge aft of the 44 percent spar. For a number of defects, acoustic emission detection preceded conventional detection by about 3,000 equivalent flying hours. Compared to periodic monitoring, continuous acoustic emission monitoring increases the number of crack advance events available for analysis and enables more secure confirmation of their source. Continuous monitoring also improves the location of crack advance sources and provides a better estimate of distributed structural noise.

DEVELOPMENT OF A METHOD TO PREDICT TRANSONIC LIMIT CYCLE OSCILLATION CHARACTERISTICS OF FIGHTER AIRCRAFT (CONTINUED)

Jos J. Meijer and Atlee M. Cunningham, Jr. 10 Apr. 1992 21 p Presented at the 33rd AIAA/ASME/AHS/ASC Structures, Structural Dynamics and Materials Conference/Dynamics Specialist Conference, Dallas, TX, 16-17 Apr. 1992 Sponsored by USAF; General Dynamics Corp.; Ministry of Defence; and National Aerospace Lab. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract NIVR-07801N)

(NLR-TP-92156-U; ETN-94-95576) Copyright Avail: Issuing Activity (European Space Agency (ESA))

The continued development of a method to predict the transonic limit cycle oscillation characteristics for a fighter aircraft is reported. An earlier analysis of steady wind tunnel data, obtained for a fighter type aircraft, indicated that shock induced and trailing edge separation play a dominant role in the development of Limit Cycle Oscillations (LCO) at transonic speeds. On the basis of these data, a semi-empirical LCO prediction method is being developed. Its preliminary version was applied to several configurations and correctly identified those which have encountered LCO. It showed the potential for application early in the design process of new aircraft to determine and understand the nonlinear aeroelastic characteristics. The method has been upgraded since. It is described in its present form and results of the latest predictions are used to further assess various parametric effects. The ultimate refinements are expected from recent unsteady wind tunnel force and pressure measurements of which a few preliminary results are analyzed. ESA

EXPANDING THE WAVERIDER DESIGN SPACE USING ARBITRARY GENERATING FLOWFIELDS Ph.D. Thesis

Frederick Ferguson 1993 227 p

Avail: Univ. Microfilms Order No. DA9327413

The present analysis deals with a quantum leap in the design space of hypersonic vehicles by carefully constructing aircraft from arbitrary flowfields. The design philosophy followed is basically that of finding a shape with a theoretically known and acceptable flowfield in the cruise condition. The ultimate goal is to obtain a complete aircraft configuration with integrated lift surface, stowage volume and propulsion unit, which will have satisfactory low speed, low supersonic speed and cruise Mach number performance. In order to construct shapes, whose behavior in an inviscid fluid stream may be calculated exactly, stream surfaces chosen according to certain rules from assumed shock shapes are replaced by solid boundaries. A combination of such a stream surface, coupled with reliable engineering approximations for the calculations of local shear stress and pressure distribution, are built up piecemeal into complete aircraft configurations. To accomplish the task of designing waveriders a new numerical technique is developed. This numerical method uses the speed and simplicity of spatial marching techniques and the efficiency of the method of characteristics. It is shown that the design process is greatly simplified. Furthermore, this method is sufficiently flexible to allow for considerable freedom of choice in the disposition of lift, volume, and base and platform shapes. Included in this analysis are methods which indicate how the lifting efficiencies of the resulting vehicles may be investigated, and to some extent, optimized. Emphasis is placed on the influence of the shock wave shape and its relationship with the aerodynamic characteristics of the resulting waverider. A systematic approach, based on the Rosenbrock optimization routine, is developed in an effort to carved waveriders with optimal aerodynamic characteristics for given dimension and free stream

conditions. A new class of viscous optimized waveriders, possessing very high L/D ratios, are presented. Finally, since the present method provides a very rapid computational procedure, it is used in parametric studies to provide preliminary data on the off design and high altitude performance of waverider configurations. (DE94-004187; UCRL-JC-115167; CONF-931193-1) Avail: CASI HC A01/MF A01

Aircraft skin thickness-loss from corrosion has been measured using dual-band infrared (DBIR) imaging on a flash-heated Boeing 737 fuselage structure. We mapped surface temperature differences of 0.2 to 0.6 C for 5 to 14% thickness losses within corroded lap splices at 0.4 seconds after the heat flash. Our procedure mapped surface temperature differences at sites without surface-emissivity clutter (from dirt, dents, tape, markings, ink, sealants, uneven paint, paint stripper, exposed metal and roughness variations). We established the correlation of percent thickness loss with surface temperature rise using a partially corroded F-18 wing box and several aluminum panels which had thickness losses from milled flat-bottom holes. We mapped the lap splice composite thermal inertia, (kpc)(sup (1/2)), which characterized shallow skin defects within the lap splice at early times (less than 0.3 s) and deeper skin defects within the lap splice at late times (greater than 0.4 s). Corrosion invaded the inside of the Boeing 737 lap splice, beneath the galley and the latrine, where we observed 'pillowing' from volume build-up of corrosion by-products. DOE

NONLINEAR MULTIBODY FORMULATION FOR ROTORCRAFT ANALYSIS Ph.D. Thesis
Nam Kook Kang 1993 281 p
Avail: Univ. Microfilms Order No. DA9325247

Rotorcraft systems include a wide range of different types of vehicles such as single, or tandem rotor helicopters and tilt rotors. Therefore a typical rotorcraft system can have several blades and rotors, fuselage and possibly wings. Similarly a variety of rotors such as articulated hingeless and bearingless rotor types have different physical characteristics, and rotor blades become complex with sweep, and twist, as well as composite materials. In view of these aspects, nonlinear multibody formulation for rotorcraft analysis has been developed. The formulation is based on the finite element method, allowing to model arbitrary complex multibody configurations. Two alternative multibody approaches are pursued and compared in terms of accuracy, computational efficiency and numerical stability and the final nonlinear multibody formulation is expressed in a single inertial system, using Cartesian coordinates to represent the configuration of each body. Elastic bodies are modeled as nonlinear beam elements which are naturally curved and twisted, and undergoing arbitrarily large deflections and rotations. Kinematic constraint elements allow an accurate modeling of multibody rotorcraft system and the constraint equations are enforced via an augmented Lagrangian formulation. After comparing various finite element and finite difference methodologies, a displacement based finite element method with Hilber-Huges-Taylor time integration scheme is used. This integration scheme introduces numerical dissipation into the time integration process to control high frequency numerical oscillations. This nonlinear multibody formulation is coupled with simplified aerodynamic model to treat realistic rotorcraft problems. Numerical results of nonlinear static problem of tension-bending-torsion coupled beam and rigid body dynamic problems show an excellent correlation with experimental data, or analytical results. Practical applications of this formulation are made for the airloads calculation in forward flight of the Sikorsky's H-34 and ground resonance prediction of the Boeing's 'Advanced Chinook' tandem helicopter. (Contract DTRS57-91-P-80859)
(PB94-142429; AD-A276593; DOT-VNTSC-FAA-93-7; DOT/FAA/CT-93/77) Avail: CASI HC A04

Periodic inspections, at a prescribed interval, for Multi-Site Damage (MSD) in longitudinal fuselage lap-joints start when the aircraft has accumulated a certain number of flights, the inspection threshold. The work reported here was an attempt to obtain justification for the threshold. It is based upon an analysis of fatigue data for lap-joints (riveted as well as riveted plus bonded) of a configuration closely resembling those in several types of aircraft. Depending upon the definition of threshold, the results show that it will be around 30,000 flights. Graphs are supplied upon the basis of which airworthiness authorities can determine a threshold in accordance with their preferred definition, and for different service conditions. NTIS

FATIGUE MANAGEMENT AND VERIFICATION OF AIRFRAMES
A. F. Blom and H. Ansell Dec. 1993 30 p Presented at the 77th AGARD Structures and Materials Panel Meeting, Bordeaux, France, 27 Sep. - 1 Oct. 1993 Sponsored by Aeronautical Research Inst. of Sweden; Saab Military Aircraft; and Swedish Defence Material Administration
(FFA-TN-1993-55; ETN-94-95858) Avail: CASI HC A03/MF A01

The methodology currently used in Sweden for fatigue management and verification of airframes is described. Applications from the new fighter aircraft JAS39 Gripen are included in order to illustrate the various concepts being considered. Additional experience from recent work on the older fighter 37 Viggen is also included to highlight certain differences in the detail analyses, stemming from rather different nominal stress levels in the two aircraft. The following are discussed: the handling of load sequences and load spectra development, stress analyses and fracture mechanics analyses, fatigue crack growth modeling, component and full scale testing, service load monitoring regarding both the dedicated test aircraft, which is used to verify basic load assumptions, and also the individual load tracking program developed for the new fighter. (AD-A275172; AL/CF-TR-1993-0134) Avail: CASI HC A06/MF A02

This study evaluated the attitude information conveyance of a new aircraft attitude display concept. The new symbology format, called the THETA symbology, was developed by integrating the shape of the conventional ADI and the transparency of the HUD into a single format. This research addressed whether or not there was a significant performance advantage or decrement incurred by the symbology integration. The THETA symbology, ADI, and HUD were evaluated during an attitude maintenance task and an attitude recovery task. The results of the study suggest few differences between the THETA and ADI formats while performance and training time were better with both the THETA symbology and the ADI than with the HUD format. The findings of the study lend support to the hypothesis that an attitude display formed of the integration of ADI and HUD type symbology will demonstrate a performance benefit over a pure HUD format. COTS+ was defined in this study as commercial off-the-shelf (COTS) products, ruggedized and militarized components, and COTS technology. This study cites the benefits of integrating COTS+ in space, postulates a COTS+ integration methodology, and develops requirements and an architecture to achieve integration. Developmental needs and concerns were identified throughout the study; these needs, concerns, and recommendations relative to their abatement are subsequently presented for further action and study. The COTS+ concept appears workable in part or in totality. No COTS+ technology gaps were identified; however, radiation tolerance was cited as a concern, and the deferred maintenance issue resurfaced. Further study is recommended to explore COTS+ cost-effectiveness, maintenance philosophy, needs, concerns, and utility metrics. The generation of a development plan to further investigate and integrate COTS+ technology is recommended. A COTS+ transitional integration program is recommended. Sponsoring and establishing technology maturation programs and COTS+ engineering and standards committees are deemed necessary and are recommended for furthering COTS+ integration in space. A RANDOM DISTRIBUTION REACTING MIXING LAYER MODEL
Richard A. Jones (Rensselaer Polytechnic Inst., Troy, NY.), C. John Marek, Leik N. Myrabo, and Henry T. Nagamatsu Mar. 1994 13 p Proposed for the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-62-52)
(NASA-TM-106517; E-8636; NAS 1.15:106517; AIAA Paper 94-3050)
Avail: CASI HC A03/MF A01

A methodology for simulation of molecular mixing, and the resulting velocity and temperature fields has been developed. The ideas are applied to the flow conditions present in the NASA Lewis Research Center Planar Reacting Shear Layer (PRSL) facility, and results compared to experimental data. A gaussian transverse turbulent velocity distribution is used in conjunction with a linearly increasing time scale to describe the mixing of different regions of the flow. Equilibrium reaction calculations are then performed on the mix to arrive at a new species composition and

temperature. Velocities are determined through summation of momentum contributions. The analysis indicates a combustion efficiency of the order of 80 percent for the reacting mixing layer, and a turbulent Schmidt number of 2/3. The success of the model is attributed to the simulation of large-scale transport of fluid. The favorable comparison shows that a relatively quick and simple PC calculation is capable of simulating the basic flow structure in the reacting and nonreacting shear layer present in the facility given basic assumptions about turbulence properties. STRUCTURAL/AERODYNAMIC BLADE ANALYZER (SAB) USER'S GUIDE, VERSION 1.0 Final Report
M. R. Morel Mar. 1994 112 p
(Contract NAS3-25266; RTOP 505-63-5B; RTOP 535-03-10; RTOP 505-62-10)
(NASA-CR-194460; E-8490; NAS 1.26:194460) Avail: CASI HC A06/MF A02

The structural/aerodynamic blade (SAB) analyzer provides an automated tool for the static-deflection analysis of turbomachinery blades with aerodynamic and rotational loads. A structural code calculates a deflected blade shape using aerodynamic loads input. An aerodynamic solver computes aerodynamic loads using deflected blade shape input. The two programs are iterated automatically until deflections converge. Currently, SAB version 1.0 is interfaced with MSC/NASTRAN to perform the structural analysis and PROP3D to perform the aerodynamic analysis. This document serves as a guide for the operation of the SAB system with specific emphasis on its use at NASA Lewis Research Center (LeRC). This guide consists of six chapters: an introduction which gives a summary of SAB; SAB's methodology, component files, links, and interfaces; input/output file structure; setup and execution of the SAB files on the Cray computers; hints and tips to advise the user; and an example problem demonstrating the SAB process. In addition, four appendices are presented to define the different computer programs used within the SAB analyzer and describe the required input decks. Author (revised)

Russia has a long tradition of achievement in ramjet research and development. The need for new and effective products has led to the establishment of ramjet research as a priority in Russian research and development. This Lecture Series will present and discuss the scientific problems associated with the development of ramjets/scramjets and turboramjets. Some specific aspects of liquid/solid ramjet development, the concepts of LH2 high efficiency RAM combustors, the results of full scale turboramjet testing, scramjet or CFD analyses, and ground flight tests will be studied. This Lecture Series, endorsed by the Propulsion and Energetics Panel of AGARD, has been implemented by the Consultant and Exchange program. For individual titles, see N94-29292 through N94-29301.

Ramjets, turboramjets, and scramjets have been studied intensively as possible propulsion systems for missiles, high velocity planes, and aerospace planes, which would use this type of propulsion during the atmospheric acceleration phase. All of these propulsion system configurations have a degree of commonality: ram ducts. This fact is discussed in this section of the Lecture Series. CASI

In this report on turboramjet engines, some of the properties of variable cycle propulsion plants based on a combination of ramjet and various turbine-type engines are considered. Various measures of engine thrust performance vs. Mach number are represented. Turboramjet engines (TRE) are classified according to their manner of energy transfer to the ramjet parts. The defining principles of essential TRE propulsion plant working parameters are considered. TRE's with various levels of thrust performance are presented. An effectiveness comparison of various combined propulsion plants for future hypersonic transport planes and a TSTO first stage with LH2 fuel is given. A preference is shown for the turboramjet engine as a universal multimode propulsion plant. The optimization of operating modes in response to changing conditions is adopted as an approach to governing the operation of a combined engine working process. Author (revised)

Solid propellant ramrockets (SPRR) combine the exclusive operational advantages of solid rockets with the higher fuel efficiency of air breathing engines. The specific feature of an SPRR which differs from a liquid fuel ramjet is the arrangement of the ram combustor in which the products of the primary burning of the solid propellant inside the gas generator are injected through nozzles and reburned. The second feature of the SPRR combustion process is that the gas by-products of primary gas generator are reburned in the ram combustor as turbulent or quasi-turbulent gas flames. Usually there is no need for special flameholders. These special features can lead to some peculiarities in the inserted booster case and to rather complicated gasified fuel supply devices. The third special (negative) feature of SPRR is the constant or programmed fuel supply rate during the flight. Hence, the problem of SPRR fuel flow rate control arises. This lecture discusses the following topics: integration of SPRR with a booster rocket engine; the energy capabilities of different ramjet solid propellants and their application; the effectiveness of secondary fuel combustion in the ram combustor; model and full scaled ramrocket ground testing; and fuel flow rate control in ramrockets. SOME PROBLEMS OF SCRAMJET PROPULSION FOR AEROSPACE PLANES. PART 1: SCRAMJET: AIMS AND FEATURES
A. Roudakov *In* AGARD, Research and Development of Ram/Scramjets and Turboramjets in Russia Dec. 1993 20 p (For primary document see N94-29291 08-07)

This lecture addresses problems of scramjet propulsion for single-stage aerospace planes. The aerospace plane main objective is acceleration of some payload up to orbital speed. It defines a requirement for the propulsion system to be frugal in the wide flight speed range under conditions of propulsion mass limitation and thrust compared with flight vehicle weight. In accordance with modern estimations, real hydrogen fuel scramjet specific impulse may be several times more than that of a rocket engine in the wide flight speed range, from Mf = 5...6 up to Mf = 15...20. But hydrogen scramjet propulsion requires significant air ram connected with high heating of vehicle structure, large hydrogen tanks (and vehicle), and special forms of the flight vehicle. As a result the scramjet advantage, as well as any other air breathing engine advantage, over the modern liquid rocket engines is not doubtless. Nevertheless scramjets can provide good efficiency in aerospace planes if each scramjet element and units are developed very carefully and have high performances. In another case, scramjet may lose

competition with liquid rocket engines and a full scale scramjet will be never created. Theoretical and experimental investigations, ground and flight model tests have demonstrated the possibility of supersonic combustion ramjet for hypersonic flights. But we must carry out serious investigations to obtain high efficiency of scramjet elements and scramjet propulsion as a whole to be sure of scramjet success in aerospace plane competition with liquid rocket engine. Integral liquid fuel ramjets (LFRJ) have some specific features influencing their arrangement and construction. Among such features are: a larger size and working duration than solid propellant ramjets (SPRR), the necessity of fuel manifolds and flameholders, the wall cooling system arrangement in the combustion chamber, and the possibility of fuel flow and nozzle position control during flight on different speed/altitude trajectories. This lecture will discuss some items concerning the mentioned LFRJ features: the integration of ram combustor and booster; duct flow instability during the ejection of booster case; fuel supply device and effective combustion in ramjet; and adaptive control of ramjet on different flight trajectories. In this report, some results of the TRE operating process including those performed on specially developed demonstrator engines are considered. Essential technical requirements and design features of the experimental TRE designed and developed at CIAM for investigatory study on a test bench are shown. Test facilities for experimental investigations of TRE in 'connected tube' manner and experimental work technology features are presented. Some results of the CIAM TRE experimental study included engine parameters on changing to ramjet operation mode variation. Working parameters in the windmilling (ramjet) mode of operation, and flow characteristics in the afterburner-ramjet combustion chamber are shown. A TRE based on TF parts characteristics matching on changing to ramjet operation mode and engine working parameter variations when going to windmilling in the ramjet mode are discussed. INVESTIGATION OF ADVANCED COUNTERROTATION BLADE CONFIGURATION CONCEPTS FOR HIGH SPEED TURBOPROP SYSTEMS. TASK 2: UNSTEADY DUCTED PROPFAN ANALYSIS COMPUTER PROGRAM USERS MANUAL Final Report, Mar. 1990 - Mar. 1991
Edward J. Hall, Robert A. Delaney, and James L. Bettner May 1991 116 p
(Contract NAS3-25270; RTOP 535-03-10)
(NASA-CR-187105; NAS 1.26:187105) Avail: CASI HC A06/MF A02

The primary objective of this study was the development of a time-dependent three-dimensional Euler/Navier-Stokes aerodynamic analysis to predict unsteady compressible transonic flows about ducted and unducted propfan propulsion systems at angle of attack. The computer codes resulting from this study are referred to as Advanced Ducted Propfan Analysis Codes (ADPAC). This report is intended to serve as a computer program user's manual for the ADPAC developed under Task 2 of NASA Contract NAS3-25270, Unsteady Ducted Propfan Analysis. Aerodynamic calculations were based on a four-stage Runge-Kutta time-marching finite volume solution technique with added numerical dissipation. A time-accurate implicit residual smoothing operator was utilized for unsteady flow predictions. For unducted propfans, a single H-type grid was used to discretize each blade passage of the complete propeller. For ducted propfans, a coupled system of five grid blocks utilizing an embedded C-grid about the cowl leading edge was used to discretize each blade passage. Grid systems were generated by a combined algebraic/elliptic algorithm developed specifically for ducted propfans. Numerical calculations were compared with experimental data for both ducted and unducted propfan flows. The solution scheme demonstrated efficiency and accuracy comparable with other schemes of this class. Author

A STUDY OF LOW EMISSIONS GAS TURBINE COMBUSTIONS Final Technical Report, 1 Oct. 1990 - 31 Jan. 1994
Henry G. Adelman 25 Apr. 1994 11 p
(Contract NCC2-699)
(NASA-CR-195763; NAS 1.26:195763) Avail: CASI HC A03/MF A01

Analytical studies have been conducted to determine the best methods of reducing NO(x) emissions from proposed civilian supersonic transports.

Modifications to the gas turbine engine combustors and the use of additives were both explored. It was found that combustors which operated very fuel rich or lean appear to be able to meet future emissions standards. Ammonia additives were also effective in removing NO(x), but residual ammonia remained a problem. Studies of a novel combustor which reduces emissions and improves performance were initiated. In a related topic, a study was begun on the feasibility of using supersonic aircraft to obtain atmospheric samples. The effects of shock heating and compression on sample integrity were modeled. Certain chemical species, including NO2, HNO3, and ClONO2 were found to undergo changes to their composition after they passed through shock waves at Mach 2. The use of detonation waves to enhance mixing and combustion in supersonic airflows was also investigated. This research is important to the use of airbreathing propulsion to obtain orbital speeds and access to space. Both steady and pulsed detonation waves were shown to improve engine performance.

AEROACOUSTIC SENSITIVITY ANALYSIS AND OPTIMAL AEROACOUSTIC DESIGN OF TURBOMACHINERY BLADES Status Report, 11 Jul. 1993 - 10 Jan. 1994

Kenneth C. Hall 10 Jan. 1994 24 p

(Grant NAG3-1433)

(NASA-CR-195786; NAS 1.26:195786) Avail: CASI HC A03/MF A01

During the first year of the project, we have developed a theoretical analysis - and wrote a computer code based on this analysis - to compute the sensitivity of unsteady aerodynamic loads acting on airfoils in cascades due to small changes in airfoil geometry. The steady and unsteady flow though a cascade of airfoils is computed using the full potential equation. Once the nominal solutions have been computed, one computes the sensitivity. The analysis takes advantage of the fact that LU decomposition is used to compute the nominal steady and unsteady flow fields. If the LU factors are saved, then the computer time required to compute the sensitivity of both the steady and unsteady flows to changes in airfoil geometry is quite small. The results to date are quite encouraging, and may be summarized as follows: (1) The sensitivity procedure has been validated by comparing the results obtained by 'finite difference' techniques, that is, computing the flow using the nominal flow solver for two slightly different airfoils and differencing the results. The 'analytic' solution computed using the method developed under this grant and the finite difference results are found to be in almost perfect agreement. (2) The present sensitivity analysis is computationally much more efficient than finite difference techniques. We found that using a 129 by 33 node computational grid, the present sensitivity analysis can compute the steady flow sensitivity about ten times more efficiently that the finite difference approach. For the unsteady flow problem, the present sensitivity analysis is about two and one-half times as fast as the finite difference approach. We expect that the relative efficiencies will be even larger for the finer grids which will be used to compute high frequency aeroacoustic solutions. Computational results show that the sensitivity analysis is valid for small to moderate sized design perturbations. (3) We found that the sensitivity analysis provided important insight into how airfoils should be modified to improve their aeroelastic stability. Using this insight, we redesigned an aeroelastically unstable cascade to produce a stable cascade. Derived from text

RADAR JET ENGINE HEALTH MONITORING PROJECT Final Report

Catherine Harrison, Nicholas Wise, Leonard Lighstone, and L. Philip Carr Jun. 1993 47 p

(ASSGI-301; CTN-94-61136) Avail: CASI HC A03/MF A01

Radar returns of aircraft exhibit jet engine modulation (JEM) lines. The JEM lines are caused by the rotating parts in the turbine engines. The radar returns from the engines suggest that it may be possible to monitor the health of the engine, more specifically blade damage and possibly blade tip rub, by using radar as a sensor. A feasibility study was conducted using continuous wave K-band and X-band radar on CF-700 and J-85 engines. Results showed that to make realistic JEM measurements, a radar with two channels (in-phase and quadrature) is required and that there are optimal viewing angles for different fan blade configurations. Radars were accordingly modified and tested including an X-band cross polarization radar for seeing further into the engine and a X-band dual channel radar. It is not yet known if the radar can see into the engine beyond the second compressor stage. Work remains to be done in order to decide whether radar as an engine health monitoring device would present any advantages over conventional maintenance methods.

FRACTOGRAPHIC AND MICROSTRUCTURAL ANALYSIS OF FATIGUE CRACK GROWTH IN Ti-6Al-4V FAN DISC FORGINGS

R. J. H. Wanhill and C. E. W. Looije 30 Sep. 1991 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B174765; NLR-TP-91142-U; ETN-94-95565) Avail: CASI HC A03

The constant amplitude and flight simulation (TURBISTAN) fatigue crack growth behavior of Ti-6Al-4V fan disc forgings, tested in an engine disc cooperative test program, was investigated by fractographic and microstructural analysis. The crack growth curve shapes and fractographic characteristics were similar. Transitions in the fatigue crack growth curves correlated with a change from structure sensitive to continuum mode crack growth, primarily in the transformed and aged beta grains, and decreased fracture surface roughness. The transitions were most probably caused by the maximum plane strain cyclic plastic zone sizes becoming equal to and exceeding the average platelet alpha packet sizes. The significance of such transitions for prediction of fatigue crack growth and service failure analysis is discussed. ESA

POTENTIAL OF THE RAMJET ENGINE FOR HYPERSONIC FLIGHT SPEEDS Ph.D. Thesis

Sami Jamil Antoun 1993 203 p

Avail: Univ. Microfilms Order No. DA9325456

Although the concept of the supersonic combustion ramjet (scramjet) is not new, the maximum flight speed that can be achieved by this power plant has not been established to date. The purpose of this dissertation is to determine the maximum flight speed at which the scramjet is capable to produce enough thrust to overcome its own external drag. In order to determine the maximum flight speed, the net thrust developed by the scramjet is compared to the external drag acting on it for flight Mach numbers 7 to 25. Using an ideal engine cycle, it will be shown that the maximum flight Mach number of the scramjet is approximately 23. When more realistic assumptions are used to include the effects of stagnation pressure loss due to viscous effects and combined friction at the wall of the combustion chamber, the maximum flight Mach number which the scramjet engine may produce is about 12. In this analysis, the flow at the end of each of the engine components is assumed to be one dimensional and in chemical and thermodynamic equilibrium. Performance losses due to incomplete mixing and combustion of fuel and air have not been considered. Dissert. Abstr.

CLOSED LOOP VIBRATIONAL CONTROL: THEORY AND APPLICATIONS Final Report, 1 Jan. 1990 - 30 Sep. 1993
Semyon M. Meerkov, Pierre T. Kabamba, and Eng-Kee Poh 15 Dec. 1993 95 p
(Contract DAAL03-90-G-0004)
(AD-A275451; ARO-27510.3-EG) Avail: CASI HC A05/MF A01

In this project, a novel control technique, referred to as Closed Loop Vibrational Control, is developed and applied to the problem of fuselage vibrations suppression in helicopter dynamics. This technique is applicable to systems where the control input enters the open loop dynamics as an amplitude of a periodic, zero average function, and this amplitude can be chosen to depend on the systems outputs. An example of such a system is the helicopter with Higher Harmonic Control (HHC) where periodic feathering of rotor blades around a fixed pitch angle is introduced in order to suppress the fuselage vibrations. For systems with this structure, a number of control-theoretic problems, including stabilizability, pole placement and robustness, have been solved, and the results are reported in this document. CONCURRENT SIMULATION AND CONSTRAINT STABILIZATION FOR FLEXIBLE MULTIBODY SYSTEMS Ph.D. Thesis

Ramesh Gopal Menon 1992 147 p
Avail: Univ. Microfilms Order No. DA9315104

This dissertation presents a family of computationally efficient methods for the simulation of large, flexible multibody systems. Nonrecursive order N formulations for the transient dynamic analysis of multibody systems can be achieved using range space methods. Unlike the recursive methods, this formulation does not rely on system topology to induce parallelism. These methods induce concurrency via the method of subdomain decomposition, and it is shown that they are amenable to implementation on the forthcoming class of highly parallel architectures. This class of formulations can be distinguished from other variants of subdomain decomposition in that redundant degrees of freedom are retained, and the coupling of substructures is achieved by explicitly calculating the coupling forces in an order N computational cost. A preconditioned conjugate gradient method is used for the range space solution, with a preconditioner motivated by the directed graph of multibody systems with no closed chains. The method is shown to be rapidly convergent for linear and nonlinear structural systems with a large number of degrees of freedom. One potential drawback of the range space formulation is the well known constraint violation drift associated with redundant formulations of transient multibody dynamics. This dissertation introduces a family of concurrent constraint violation stabilization algorithms that retain the order N computational cost of the range space formulation, while ensuring simulation fidelity. The hybrid methods introduced are based upon penalty multibody formulations and augmented Lagrangian formulations. Explicit bounds on measures of the constraint violation are presented. It is shown that, in the augmented Lagrangian method, the number of fixed iterations per time step dictate the diameters of the attractors of constraint violations in phase space. Several numerical examples of simulation and control are presented including simulations of the Space Station Freedom, the NASA Langley control structure interaction evolutionary model, and nonlinear, multirigid bodies articulating in space. AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF LEADING EDGE EXTENSIONS ON DIRECTIONAL STABILITY AND THE EFFECTIVENESS OF FOREBODY NOSE STRAKES Ph.D. Thesis
An-Kuo Fu 1992 197 p
Avail: Univ. Microfilms Order No. DA9323014

Low speed wind tunnel testing was conducted at Aeronautical Research Laboratory in Taiwan, ROC, using a generic configuration, to investigate the effect of leading-edge extensions (LEX) on directional stability and the effectiveness of forebody nose strakes. To help interpret the wind tunnel measurements, flow visualization including dye and laser sheet was also conducted. It was found that for the present configuration, the LEX vortices dominated the flow field such that the forebody vortices were depressed to stay close to the body surface. Because of this, the nose strakes on this configuration were found to be ineffective in reducing directional instability and producing control moment with a single strake. Directional instability for the configuration with the LEX's was mainly caused by the vertical tail. However, for the configuration with a single small nose strake at very high angles of attack, the instability was caused by a second forebody vortex formed under the nose strake which stayed close to the body surface. Using a single large nose strake, effectiveness for yaw control was significantly improved. However, for sideslip control, the proper forebody side for its deployment depends on the angle of attack. In addition, with a pair of large nose strakes, the untrimmed yawing moment was almost eliminated at zero sideslip. A bi-stable condition was identified for the configuration without the LEX's at alpha = 46 deg. in the water tunnel and 48 deg. in the wind tunnel. For the baseline configuration with the LEX's, a bi-stable condition was also found at alpha = 55 deg.

DECOUPLED FLIGHT CONTROL SYSTEM DESIGN USING THE SINGULAR PERTURBATION METHOD
Sukjune Park 1992 209 p
Avail: Univ. Microfilms Order No. DA9311976

A new approach is developed to design the high gain output feedback with proportional plus integral (P-I) controller. The singular perturbation theory is utilized for the theoretical development. This approach is simpler and more comprehensive than the other methods. The controller produces desirable closed-loop response with minimal interaction between outputs. The new design method is applied to the design of decoupling flight control systems for the full aircraft model (i.e., lateral and longitudinal dynamics). The complete process used to obtain a decoupling flight control law is presented. A robustness study is included to test the controller performance with parameter variations. The results show that the controller is robust with respect to varying maneuver commands. Also, this study includes the six degree of freedom nonlinear simulation to validate the design method. The nonlinear simulation results show that output-feedback solutions from the linear case satisfy the required conditions for application to nonlinear systems. A computer aided design program is developed to assist in the interactive design process. Dissert. Abstr.

A NOVEL APPROACH TO NOISE-FILTERING BASED ON A GAIN-SCHEDULING NEURAL NETWORK ARCHITECTURE
T. Troudet (Sverdrup Technology, Inc., Brook Park, OH.) and W. Merrill Apr. 1994 10 p
(Contract NAS3-25266; RTOP 584-03-11)
(NASA-TM-106563; E-8739; NAS 1.15:106563) Avail: CASI HC A02/MF A01

A gain-scheduling neural network architecture is proposed to enhance the noise-filtering efficiency of feedforward neural networks, in terms of both nominal performance and robustness. The synergistic benefits of the proposed architecture are demonstrated and discussed in the context of the noise-filtering of signals that are typically encountered in aerospace control systems. The synthesis of such a gain-scheduled neurofiltering provides the robustness of linear filtering, while preserving the nominal performance advantage of conventional nonlinear neurofiltering. Quantitative performance and robustness evaluations are provided for the signal processing of pitch rate responses to typical pilot command inputs for a modern fighter aircraft model. DESIGN AND FABRICATION OF FORWARD-SWEPT COUNTERROTATION BLADE CONFIGURATION FOR WIND TUNNEL TESTING Final Report
G. H. Nichols 1 Mar. 1994 164 p
(Contract NAS3-25269)
(NASA-CR-194868; NAS 1.26:194868) Avail: CASI HC A08/MF A02

Work performed by GE Aircraft on advanced counterrotation blade configuration concepts for high speed turboprop system is described. Primary emphasis was placed on theoretically and experimentally evaluating the

aerodynamic, aeromechanical, and acoustic performance of GE-defined counterrotating blade concepts. Several blade design concepts were considered. Feasibility studies were conducted to evaluate a forward-swept versus an aft-swept blade application and how the given blade design would affect interaction between rotors. Two blade designs were initially selected. Both designs involved in-depth aerodynamic, aeromechanical, mechanical, and acoustic analyses followed by the fabrication of forward-swept, forward rotor blade sets to be wind tunnel tested with an aft-swept, aft rotor blade set. A third blade set was later produced from a NASA design that was based on wind tunnel test results from the first two blade sets. This blade set had a stiffer outer ply material added to the original blade design, in order to reach the design point operating line. Detailed analyses, feasibility studies, and fabrication procedures for all blade sets are presented. Author (revised)

THE NOZZLE ACOUSTIC TEST RIG: AN ACOUSTIC AND AERODYNAMIC FREE-JET FACILITY

Raymond S. Castner Apr. 1994 12 p Presented at the 18th AIAA Aerospace Ground Testing Conference, Colorado Springs, CO, 20-23 Jun. 1994; sponsored by AIAA

(RTOP 505-62-84)

(NASA-TM-106495; E-8485; NAS 1.15:106495; AIAA Paper 94-2565)

Avail: CASI HC A03/MF A01

The nozzle acoustic test rig (NATR) was built at NASA Lewis Research Center to support the High Speed Research Program. The facility is capable of measuring the acoustic and aerodynamic performance of aircraft engine nozzle concepts. Trade-off studies are conducted to compare performance and noise during simulated low-speed flight and takeoff. Located inside an acoustically treated dome with a 62-ft radius, the NATR is a free-jet that has a 53-in. diameter and is driven by an air ejector. This ejector is operated with 125 lb/s of compressed air, at 125 psig, to achieve 375 lb/s at Mach 0.3. Acoustic and aerodynamic data are collected from test nozzles mounted in the free-jet flow. The dome serves to protect the surrounding community from high noise levels generated by the nozzles, and to provide an anechoic environment for acoustic measurements. Information presented in this report summarizes free-jet performance, fluid support systems, and data acquisition capabilities of the NATR.

CLEANROOM ENGINEERING HANDBOOK. VOLUME 3: PROJECT EXECUTION IN THE CLEANROOM ENVIRONMENT

Ara Kouchakdjian, Richard H. Cobb, Alan R. Hevner, and James A. Whittaker 31 Jul. 1993 69 p

(Contract F19628-88-C-0032)

(AD-A275860) Avail: CASI HC A04/MF A01

This is one of a series of six engineering handbooks prepared for and used by the engineering staff at Picatinny Arsenal for the STARS technology transfer demonstration. The handbooks define the engineering process and algorithms that will be used in Cleanroom projects. They are designed to provide support to trained engineers using Cleanroom Engineering, not to substitute for training. This handbook, Volume 3, provides managers and team leaders with guidance in the planning, directing, and controlling of Cleanroom projects. Project execution is the planning for, and the controlling of the solution to the four major decisions within a software project. These decisions are: (1) to assign tasks to specific team members in the execution of the project; (2) to determine the expected completion date for some phase of the project; (3) to determine if the progress made toward developing the desired software and the resources consumed to date are in balance with each other and with the project's Business Plan; and (4) to determine if some aspect of the design is acceptable and the design effort should continue in the current direction or if the direction should be altered. If the direction is to be altered then a replanning effort must be initiated. This volume covers topics such as completion conditions, metrics collection, forms driven process management system, file and tool reference table, and an automated process management system named CEPA (Cleanroom Engineering Process Assistant). DTIC

N94-28753# IBM Federal Systems Div., Gaithersburg, MD.

CLEANROOM ENGINEERING HANDBOOK. VOLUME 4. SPECIFICATION TEAM PRACTICES

Ara Kouchakdjian, Richard H. Cobb, Alan R. Hevner, and James A. Whittaker 31 Jul. 1993 69 p

(Contract F19628-88-D-0032)

(AD-A275861) Avail: CASI HC A04/MF A01

This is one of a series of six engineering handbooks prepared for and used by the engineering staff at Picatinny Arsenal for the STARS technology transfer demonstration. The handbooks define the engineering process and algorithms that will be used in Cleanroom projects. They are designed to provide support to trained engineers using Cleanroom Engineering, not to substitute for training. This handbook, Volume 4, explains the set of specific tasks performed by the Cleanroom Specification Team for each cycle of a project. Specification tasks are described and the relationship among tasks are defined. The Cleanroom specification team's mission is to create the system specification in six specification volumes. Templates are proposed as recommended formats for the presentation of information and tasks results. Techniques for revising the specifications throughout the system life cycle are described. The Cleanroom process model for software system development projects is presented in Volume 1 - Cleanroom Process Overview - of this series of Cleanroom Handbooks. This handbook, Volume 4, describes the activities of the Specification Team for each cycle of project development. The specification activity may include the preparation of both system and software specifications, depending on the needs and status of the project. Specifications define the requirements placed on the system so it can satisfy its mission and the behavior the system must exhibit to fulfill the assigned requirements. A system specification defines requirements and behavior for a solution which integrates some combination of hardware, software, communications, human behavior, etc. DTIC

N94-28772 IBM Federal Systems Div., Gaithersburg, MD.

CLEANROOM ENGINEERING HANDBOOK. VOLUME 2: ORGANIZATION AND PROJECT FORMATION IN THE CLEANROOM ENVIRONMENT

31 Jul. 1993 55 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F19628-88-D-0032)

(AD-A275809) Avail: CASI HC A04

The purpose of this handbook is to provide managers with guidance in developing plans on the organization and project levels for the development of software using the Cleanroom process. Additionally, guidance on directing and controlling the implementation of the plan will be presented to help managers ensure that projects are properly executed. Planning, directing, and controlling are just a few of the aspects of a manager's role in the Cleanroom process. The planning, directing, and controlling requirements for managers at different levels differ as do the requirements at different stages of the project. DTIC

GRANULAR BASES FOR HEAVILY LOADED PAVEMENTS Final Report, Feb. 1988 - Dec. 1990

W. K. Chan and S. F. Brown Mar. 1993 170 p

(AD-A275171; AFCESA/CEL-TR-91-06) Avail: CASI HC A08/MF A02

This research improves the understanding of the permanent deformation characteristics of granular materials under repeated, reversed shear loadings in flexible pavements. In the laboratory, triaxial tests provided vertical repeated loadings, and a hollow cylinder apparatus was used to apply reversing shear stresses and associated rotating principal planes. The laboratory tests were analogous to larger scale tests that were run, using vertical plate and tire loadings. It was found that higher material densities lead to large improvements in permanent deformation resistance, and permanent deformation is significantly more when stresses are reversed in both the laboratory and in the field. The findings were validated using two fully-instrumented pilot scale trafficking tests. DTIC

ASPHALTIC CONCRETE PERFORMANCE UNDER HEAVY FIGHTER AIRCRAFT LOADING Final Report, Apr. 1988 - Nov. 1990

D. A. Timian, S. M. Dass, W. C. Dass, R. H. Sues, and M. B. Hardy Feb. 1993 359 p

(AD-A275046; AFCESA/ESL-TR-91-26; XC-AFCESA/ESL) Avail: CASI HC A16/MF A03

Rutting of asphaltic concrete pavements is rapidly becoming a cause for concern among AF civil engineers. Modern fighter aircraft often have operating tire pressures well above the capacity of the existing pavements. To reduce rutting, a mix design technique that explicitly considers the expected loading was investigated. Pavement test sections were constructed and trafficked by high pressure tires. Variations in test sections included mix design (Marshall and gyratory), airfield design (4- and 6-inch flexible and rigid composite), and wheel loading (F-15C/D). Pavement loading was monitored throughout trafficking, including dynamic load magnitude, position, and velocity. Pavement response was measured by taking profilographs before, during, and after trafficking. Damage parameters were defined and calculated to evaluate test section response and performance. Damage varied significantly between test sections, with the most obvious factors being the mix design and the base layer support. The gyratory test sections outperformed their Marshall counterparts with the gyratory composite section performing the best. This study has shown that pavements can be designed using gyratory methods. However, improvements in base layer performance are needed to improve the overall performance of flexible airfield pavements. DTIC

ROOFTOP EMERGENCY HELIPORTS Final Report

William T. Sampson, III, Sandra Henninger, and Richard S. Fixler Jun. 1993 61 p

(Contract DTFA01-87-C-00014)

(DOT/FAA/RD-93/2) Avail: CASI HC A04/MF A01

The research for this project included an in-depth analysis of high-rise fire incidents in which helicopters have been used. Following this effort, a survey was conducted of building codes that were applicable to the construction of heliports and helistops on the roofs of high-rise buildings. These codes were examined to determine common and uncommon elements and to identify strengths and weaknesses. After analyzing this data, the FAA's Heliport Design Advisory Circular (AC) 150/5390-2 was reviewed. This data was then used to develop recommendations for additions or changes to the AC. Author

LARGE SCALE CRYOGENIC FLUID SYSTEMS TESTING

May 1992 13 p Original contain color illustrations

(NASA-TM-109735; B-0426; NAS 1.15:109735) Avail: CASI HC A03/MF A01; 6 functional color pages

NASA Lewis Research Center's Cryogenic Fluid Systems Branch (CFSB) within the Space Propulsion Technology Division (SPTD) has the ultimate goal of enabling the long term storage and in-space fueling/resupply operations for spacecraft and reusable vehicles in support of space exploration. Using analytical modeling, ground based testing, and on-orbit experimentation, the CFSB is studying three primary categories of fluid technology: storage, supply, and transfer. The CFSB is also investigating fluid handling, advanced instrumentation, and tank structures and materials. Ground based testing of large-scale systems is done using liquid hydrogen as a test fluid at the Cryogenic Propellant Tank Facility (K-site) at Lewis' Plum Brook Station in Sandusky, Ohio. A general overview of tests involving liquid transfer, thermal control, pressure control, and pressurization is given. Derived from text

APPLICATION OF FUZZY LOGIC TO THE CONTROL OF WIND TUNNEL SETTLING CHAMBER TEMPERATURE

David A. Gwaltney and Gregory L. Humphreys Mar. 1994 16 p

(RTOP 505-70-59-03)

(NASA-TM-109105; NAS 1.15:109105) Avail: CASI HC A03/MF A01

The application of Fuzzy Logic Controllers (FLC's) to the control of nonlinear processes, typically controlled by a human operator, is a topic of much study. Recent application of a microprocessor-based FLC to the control of temperature processes in several wind tunnels has proven to be very successful. The control of temperature processes in the wind tunnels requires the ability to monitor temperature feedback from several points and to accommodate varying operating conditions in the wind tunnels. The FLC has an intuitive and easily configurable structure which incorporates the flexibility required to have such an ability. The design and implementation of the FLC is presented along with process data from the wind tunnels under automatic control. Author

THE 1992 REPORT ON THE NEXT GENERATION ULTRA CLEAN TECHNOLOGY FOR ADVANCED MICROFABRICATION

Mar. 1993 666 p In JAPANESE

(DE94-744171; ETDE/JP-MF-94744171) Avail: CASI HC A99/MF A06

The paper studies the next generation ultraclean technology for the manufacture of ultrahigh integrated and ultrahigh functional electronic devices. To effectively fabricate ultrahigh performance LSI at a low cost, the first thing needed is checking of the capital investment. The equipment cost makes up 74 percent of the capital investment. It becomes extremely important to reduce the process number by simplification of device structure, to increase operational rates of the equipment, and to reduce the number of the equipment. On the other hand, it is necessary to give the equipment continued cleaning in order to prevent a decrease in yield caused by attachment of foreign substances and to assure quality. It is also necessary to introduce facilities with such high performance as plasma in-situ cleaning. The paper gives detailed explanations of the future semiconductor manufacturing system and fabrication facilities technology and the technology for the reactive/corrosive particular gas which is expected to be increasingly used for CVD and RIE (reactive ion etching). Detailed explanations are also given of the water evaluation technology, microvibration prevention necessary for ultra-microprocessing, the contamination control system, and the water surface processing and measuring technology. CORRECTION OF X HOT-WIRE MEASUREMENTS FOR GRADIENTS NORMAL TO THE PLANE OF THE WIRES

J. H. M. Gooden 9 Jul. 1992 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB94-125473; NLR-TP-95592; ETN-94-95592) Avail: CASI HC A04

A gradient correction method, which allows correction of the results obtained from X hot wire measurements for flow gradients normal to the plane of the hot wires, is described. The influence of these gradients on the hot wire response is determined from the hot wire response equations. A data processing method which allows a correction of the measured data after the measurements have been completed is described. The method was applied to hot wire measurements of the mean and fluctuating flow velocities in the turbulent wake shed from a two dimensional wing above a single trailing edge flap. ESA

A MODERNISED HST OF NLR
F. Jaarsma, J. Smith, and R. K. vanderDraai 31 Oct. 1992 22 p Presented at the European Windtunnels and Forum on Windtunnel Test Techniques, Southampton Univ., England, 14-17 Sep. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B179220; NLR-TP-92420-U; ETN-94-95961) Avail: CASI HC A03

The modernization underway and plans for the future of the High Speed Tunnel (HST) are reported. The improvement comprised three main objectives, namely: improvement of testing capabilities; improvement of Reynolds number range; and improvement of productivity. Because of budget limitations the total plan will be executed in phases. The first phase, now under full execution, concerns the following more specific items: extension of test section length to reduce buoyancy effects; adaptability to two different test section heights (1.6 and 1.8 m) allowing extended incidence range; new model support system allowing a selection between slender sting support boom with limited incidence range (30 deg), double roll sting boom with moderate incidence range (30 deg in a single sweep) and limited yaw (+ and -10 deg), or articulated sting boom with large incidence range (50 deg) and large yaw (+ and - 30 deg); automated tunnel operation for improved productivity and improved accuracy; and modernization of the controls of the power plant. Wall and support interference effects were studied in detail in order to arrive at improved mechanical systems and correction methods. Further improvements planned in the future include application of adaptive walls and an increase of power to extend the range in terms of Reynolds number testing. ESA

ANALYSIS OF FLUCTUATING STATIC PRESSURE MEASUREMENTS IN A LARGE HIGH REYNOLDS NUMBER TRANSONIC CRYOGENIC WIND TUNNEL Ph.D. Thesis
William B. Igoe 1993 258 p
Avail: Univ. Microfilms Order No. DA9329869

Dynamic measurements of fluctuating static pressure levels were made using flush mounted high frequency response pressure transducers at eleven locations in the circuit of the National Transonic Facility (NTF) over the complete operating range of this wind tunnel. Measurements were made at test section Mach numbers from 0.2 to 1.2, at pressure from 1 to 8.6 atmospheres and at temperatures from ambient to -250 F, resulting in dynamic flow disturbance measurements at the highest Reynolds numbers available in a transonic ground test facility. Tests were also made independently at variable Mach number, variable Reynolds number and variable drivepower, each time keeping the other two variables constant thus allowing for the first time, a distinct separation of these three important variables. This report contains a description of the NTF emphasizing its flow quality features, details on the calibration of the instrumentation, results of measurements with the test section slots covered, downstream choke, effects of liquid nitrogen injection and gaseous nitrogen venting, comparisons between air and nitrogen, isolation of the effects of Mach number, Reynolds number and fan drive power, and identification of the sources of significant flow disturbances. The results indicate that primary sources of flow disturbance in the NTF may be edge-tones generated by test section sidewall reentry flaps and the venting of nitrogen gas from the return leg of the tunnel circuit between turns 3 and 4 in the cryogenic mode of operation. The tests to isolate the effects of Mach number, Reynolds number and drive power indicate that Mach number effects predominate. A comparison with other transonic wind tunnels shows that the NTF has low levels of test section fluctuating static pressure especially in the high subsonic Mach number range from 0.7 to 0.9. 'REAL TIME' AND THE NLR AERODYNAMIC FACILITIES
R. K. vanderDraai 23 Mar. 1992 16 p Presented at the NLUUG Conference, Ede, Netherlands, 6 May 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B173626; NLR-94-92113-U; ETN-94-95573) Avail: CASI HC A03

Reasons for the real time characteristics of the computer systems directly connected to a wind tunnel, and which are used for data acquisition, process control and data processing, are given. The choice of a computer to perform any of these tasks is described, and strategies to do so are given. An example of choosing a real time control system for use in aerodynamic facilities is outlined. The choice of the computer was made in the HP computer domain. Therefore, the choice between UNIX or a real time environment was needed. It turned out that the UNIX (HP-UX) computers (HP9000) do not respond as fast as RTE-A computers, while the RTE-A computers (HP1000) are not as fast as the HP9000 computers. After precise definition of the problem and careful analysis of the computer properties for this particular problem, HP1000 RTE-A machines were chosen. ESA

This report reviews the protein crystal growth experiments under microgravity. The objective is to verify the potentials of protein crystal growth in the spacecraft. Principles of crystal growth, examples of the actual experiments such as cytochrome oxidized enzymes crystallization are introduced. The following concluding remarks were confirmed: (1) crystal growth is slower in microgravity. Crystal nucleus generation and crystal growth take place in a diffused rate-determining step due to lack of weight differences between solute and protein molecules; (2) protein molecules behave differently at crystal nucleus generation. Even in the same crystallization conditions, nucleus generation strongly depends on the electric charge on protein molecule surfaces, generating crystal nuclei with different physical properties from those of the earth counterparts; and (3) single crystals in high quality are obtained in microgravity, however, this does not necessarily depend on the shape or size of the single crystals. The possible cause is that because crystal nucleus generation is mainly determined by

the physical properties on the molecule surfaces, molecules meet more accurately, making better molecule arrangement within crystal nuclei.

Materials with super high purity can be obtained that benefit from the evolution in material refining and high-vacuum technologies for these past ten years. Taking advantages of microgravity environment, amorphous semiconductors made a remarkable improvement both in quality and quantity. Although there has not been an experiment utilizing the merit of high-vacuum environment, the environment is essential for film fabrication, from spattering to MBE (Molecular Beam Epitaxy) and plasma CVD (Chemical Vapor Deposition). It also has a potential function as a heat sink. Space is considered to be a favorable environment for many things including the followings that were investigated: semiconductor joining by atomic adhesion, fabrication of thin films of diamond and amorphous silicon alloys, CVD processes, production of super-minute grains, light element analysis by SIMS (Secondary Ion Mass Spectrometry), and anti-proton generation by laser accelerators. A solar breeder allows for the amount of solar batteries transported from the earth to be minimized, cutting down transportation costs tremendously. This report reviews the potentials of material processing in space. Processing technologies of spacecraft construction materials, thin solid films, and fine alloys are reviewed. Light element analyzing method and antiproton storing technology for liquid metal MHD (Magnetohydrodynamic) power generator are also reviewed.

APPLICATION OF EXTENDED LAGRANGE SERIES TO THE PRECISE DETERMINATION OF GLOBAL POSITIONING SATELLITE ORBITS M.S. Thesis [APPLICATION DES SERIES DE LAGRANGE ETENDUES A LA DETERMINATION PRECISE DES ORBITES DES SATELLITES GPS]
Caroline Huot Sep. 1993 128 p In FRENCH
(ISBN-0-315-85724-2; CTN-94-61152) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A new semi-analytical method is presented for solving the calculation of the perturbed orbits of Global Positioning System (GPS) satellites. Preliminary notions concerning coordinates, Keplerian orbits, and the perturbed orbit are established. The basic principles of the analytical and numerical method are introduced along with the models of the principal perturbations affecting the GPS satellites. Different methods of orbit calculation are reviewed to demonstrate the main advantages and drawbacks of each. A comparison proves that the method of extended Lagrange series has many advantages. Contrary to Cowell's method, the extended Lagrange series method does not require any starting algorithm. The proposed method is distinguished from other techniques of integration by its simple formulation and for its facility in analyzing one or many perturbations. Results obtained using the MicroCosm program are presented which indicate that calculation of the orbit by the extended Lagrange series method is accurate to within 4 cm and 70 cm for short arcs of 6 and 10 hours respectively.

OPTIMAL LOW-THRUST, EARTH-MOON TRAJECTORIES Ph.D. Thesis
Craig Allen Kluever 1993 146 p
Avail: Univ. Microfilms Order No. DA9321183

A variety of optimal trajectories from a circular low-Earth parking orbit to a circular low-lunar parking orbit are computed for a range of low-thrust spacecraft. The problem is studied in the context of the classical restricted three-body problem. Minimum-fuel, planar trajectories with a fixed thrust-coast-thrust engine sequence are computed for both a 'high-end' low-thrust spacecraft and 'moderate' low-thrust nuclear electric propulsion (NEP) spacecraft. Since a low-thrust trajectory is a long duration transfer with slowly developing spirals about the Earth and Moon, the minimum-fuel Earth-Moon trajectory is obtained by formulating and successively solving a hierarchy of subproblems. The subproblems include optimal Earth-escape and Moon-capture trajectories and sub-optimal translunar trajectories. The complete minimum-fuel trajectory problem is eventually solved using a 'hybrid' direct/indirect method which utilizes the benefits of a direct optimization method and an indirect method from optimal control theory. Minimum-fuel transfers are also computed using a switching function structure which results in multiple thrust and coast arcs. In addition, a new combined vehicle and trajectory optimization problem of maximum payload fraction is formulated and solved. Finally, 3-D minimum-fuel trajectories are obtained for both the 'high-end' and 'moderate' low-thrust spacecraft. Numerical results are presented for various optimal Earth-Moon trajectories.

Testing laboratories can - if they fulfil the requirements - be appointed as notified bodies responsible for certain EC Directives. The notification process has been analyzed from the viewpoint of testing laboratories. The tasks the testing laboratory must take on board when acting as a notified body have been identified. As testing laboratories can also act as notified bodies, many laboratories will expand their activities in that direction. They have to, of course, demonstrate their capability, but the decision will mainly be related to expected market developments. The questions of financing certain infrastructural costs as well as of challengability are open for further discussion. NTIS

In 1987 a NASA panel recommended the creation of the Mission to Planet Earth. This mission was intended to apply to remote sensing experience of the space community to earth remote sensing to enhance the understanding of the climatological processes of our planet and to determine if, and to what extent, the hydrological cycle of Earth is being affected by human activity. One of the systems required for the mission was a wide scanning, high gain reflector antenna system for use in radiometric remote sensing from geostationary orbit. This work describes research conducted at Virginia Tech into techniques for beam scanning offset Cassegrain reflector antennas by subreflector translation and rotation. Background material relevant to beam scanning antenna systems and offset Cassegrain reflector antenna system is presented. A test case is developed based on the background material. The test case is beam scanned using two geometrical optics methods of determining the optimum subreflector position for the desired scanned beam direction. Physical optics far-field results are given for the beam scanned systems. The test case system is found to be capable of beam scanning over a range of 35 half-power beamwidths while maintaining a 90 percent beam efficiency or 50 half-power beamwidths while maintaining less than I dB of gain loss during scanning. In the reference scenario of the ROSETTA CNRS mission, the Sample Acquisition System is mounted on the Comet Lander. Its tasks are to acquire three kinds of cometary samples and to transfer them to the Earth Return Capsule. Operations are to be performed in vacuum and microgravity, on a probably rough and dusty surface, in a largely unknown material, at temperatures in the order of 100 K. The concept and operation of the Sample Acquisition System are presented. The design of the prototype corer and surface sampling tool, and of the equipment for testing them at

cryogenic temperatures in ambient conditions and in vacuum in various materials representing cometary soil, are described. Results of recent preliminary tests performed in low temperature thermal vacuum in a cometary analog ice-dust mixture are provided. Author

Robotic systems have been proposed as a means of accomplishing assembly and maintenance tasks in space. The desirable characteristics of these systems include compact size, low mass, high load capacity, and programmable compliance to improve assembly performance. In addition, the mechanical system must transmit power in such a way as to allow high performance control of the system. Efficiency, linearity, low backlash, low torque ripple, and low friction are all desirable characteristics. This work presents a pitch-yaw joint module designed and built to address these issues. Its effectiveness as a two degree-of-freedom manipulator using natural admittance control, a method of force control, is demonstrated. Author (revised)

Avail: CASI HC A03/MF A03

A Mars rover prototype vehicle named Rocky 4 was designed and built at JPL during the fall of 1991 and spring 1992. This vehicle is the fourth in a series of rovers designed to test vehicle mobility and navigation software. Rocky 4 was the first attempt to design a vehicle with 'flight like' mass and functionality. It was consequently necessary to develop highly efficient mechanisms and structures to meet the vehicles very tight mass limit of 3 Kg for the entire mobility system (7 Kg for the full system). This paper will discuss the key mechanisms developed for the rover's innovative drive and suspension system. These are the wheel drive and strut assembly, the rocker-bogie suspension mechanism and the differential pivot. The end-to-end design, analysis, fabrication and testing of these components will also be discussed as will their performance during field testing. The lessons learned from Rocky 4 are already proving invaluable for the design of Rocky 6. Rocky 6 is currently being designed to fly on NASA's MESUR mission to Mars scheduled to launch in 1996. The Waves In Space Plasma (WISP) flight experiment requires a 50-meter-long deployable dipole antenna subsystem (DASS) to radiate radio frequencies from the STS Orbiter cargo bay. The transmissions are to excite outer ionospheric plasma between the dipole and a free-flying receiver (Spartan) for scientific purposes. This report describes the singular DASS design requirements and how the resulting design satisfies them. A jettison latch is described in some detail. The latch releases the antenna in case of any problems which might prevent the bay doors from closing for re-entry and landing of the Orbiter. Author

The Wake Shield Facility (WSF) is a space transportation system (STS) payload that is scheduled for launch on STS-60 in November, 1993. It is being designed, tested and integrated into the STS by Space Industries Inc. for the University of Houston's Space Vacuum Epitaxy Center, a NASA Center for the Commercial Development of Space. The WSF is composed of two main components: a cross-bay carrier and a free-flying experimental platform. The WSF's primary objective is the epitaxial growth of thin films by controlled beam techniques in the ultra-high vacuum that exists in the wake of the free-flyer. The Retention Latch Mechanism (RLM) has been developed to act as the structural interface between the free-flyer and the carrier. Author

Avail: CASI HC A02/MF A03

Transmitting and changing the characteristics of force and stroke is a requirement in nearly all mechanisms. Examples include changing linear to rotary motion, providing a 90 deg change in direction, and amplifying stroke or force. Requirements for size, weight, efficiency and reliability create unique problems in spacecraft mechanisms. Flexible metal band and cam drive systems provide powerful solutions to these problems. Band drives, rack and pinion gears, and bell cranks are compared for effectiveness. Band drive issues are discussed including materials, bend radius, fabrication, attachment and reliability. Numerous mechanisms are shown which illustrate practical applications of band drives. Author

The Shuttle Radar Laboratory (SRL) is scheduled for launch in December of 1993 on the first of its two missions. The SRL has three major radar instruments: two distributed phased-array antennas, which make up the Spaceborne Imaging Radar-C System (SIR-C) and are capable of being electronically steered, and one X-Band Synthetic Aperture Radar (X-SAR), which is pointed mechanically by a suite of mechanisms. This paper will describe these mechanisms and summarize the development difficulties that were encountered in bringing them from the design stage through prototype development and protoflight testing. This paper describes the Honeywell-developed Optical Chopper Assembly (OCA), a component of Mars Observer spacecraft's Pressure Modulator Infrared Radiometer (PMIRR) science experiment, which will map the Martian atmosphere during 1993 to 1995. The OCA is unique because of its constant accurate rotational speed, low electrical power consumption, and long-life requirements. These strict and demanding requirements were achieved by use of a number of novel approaches. Author

The bus actuators are the heart and at the same time the Achilles' heel of accurate spacecraft stabilization systems, because both their performance and their perturbations can have a deciding influence on the achievable pointing accuracy of the mission. The main task of the attitude actuators, which are mostly wheels, is the generation of useful torques with sufficiently high bandwidth, resolution and accuracy. This is because the bandwidth of the whole attitude control loop and its disturbance rejection capability is dependent upon these factors. These useful torques shall be provided, without - as far as possible - parasitic noise like unbalance forces and torques and harmonics. This is because such variable frequency perturbations excite structural resonances which in turn disturb the operation of sensors and scientific instruments. High accuracy spacecraft will further require bus actuators for the three linear degrees of freedom (DOF) to damp structural oscillations excited by various sources. These actuators have to cover the dynamic range of these disturbances. Another interesting feature, which is not necessarily related to low noise performance, is a gimballing capability which enables, in a certain angular range, a three axis attitude control with only one wheel. The herein presented Teldix MWX, a five degree of freedom Magnetic Bearing Momentum Wheel, incorporates all the above required features. It is ideally suited to support, as a gyroscopic actuator in the attitude control system, all High Pointing Accuracy and Vibration Sensitive space missions. Author

Avail: CASI HC A03/MF A03

A lubricant screening test fixture has been devised in order to satisfy the need to obtain lubricant performance data in a timely manner. This fixture has been used to perform short-term tests on potential lubricants for several spacecraft applications. The results of these tests have saved time by producing qualitative performance rankings of lubricant selections prior to life testing. To date, this test fixture has been used to test lubricants for 3 particular applications. The qualitative results from these tests have been verified by life test results and have provided insight into the function of various anti-wear additives. Author

Avail: CASI HC A03/MF A03

The Michelson Doppler Imager (MDI) is a scientific instrument aboard the Solar and Heliospheric Observatory (SOHO) spacecraft. In 1995, the spacecraft will be put into a halo orbit about the L1 Lagrangian point (equal Sun and Earth gravity). The MDI looks at the sun continuously and takes a picture with a large format CCD camera every 3 seconds. The design goal of the mission is 6 years, so over 60 million pictures will be taken. The sun, being a high intensity source, provides a signal with a single pixel noise level of 0.2 percent. Many images are combined to measure the oscillatory motion of the sun so very high performance is required of the mechanisms in order that they not add noise to the data. The MDI instrument is made up of two parts, the electronics package and the optics package. This paper describes the design and testing of three mechanisms on the MDI which are required to operate large numbers of times. Derived from text

PARACHUTE SWIVEL MECHANISM FOR PLANETARY ENTRY **c18**
R. Birner, J. Kaese, F. Koller, E. Muehlner, and H.-J. Luhmann *In* NASA. Ames Research Center, The 27th Aerospace Mechanisms Symposium May 1993 p 237-254 Sponsored by ESA and DASA (For primary document see N94-29627 08-15)
Avail: CASI HC A03/MF A03

A parachute swivel mechanism (PSM) for planetary entry missions such as a Mars probe (MARSNET) or return of cometary material samples (ROSETTA mission) has been developed. The purpose of the PSM is to decouple the spin of the probe from the parachute, with low friction torque, during both the deployment and descent phases. Critical requirements are high shock loads, low friction, low temperatures, and several years of storage in the deep space environment (during the cruise phase of the probe, prior to operation). The design uses a main thrust ball bearing to cope with the load requirement and a smaller thrust ball bearing for guiding of the shaft. Except for use on the Viking and Galileo swivels, it appears that this type of bearing has very rarely been employed in space mechanisms, so that little is known of its friction behavior with dry lubrication. A slip

ring assembly allows the transfer of electrical power for post-reefing of the parachute. A test program has been conducted covering the environmental conditions of Mars entry and Earth reentry. This paper describes requirement constraints, model missions of planetary entries, a bearing trade-off, analyses performed, design details, the lubrication system, and test results (friction torque versus load/spin rate). In addition, the design of the test rig is addressed. Author (revised)

THE SOLAR ANOMALOUS AND MAGNETOSPHERIC PARTICLE EXPLORER (SAMPEX) YO-YO DESPIN AND SOLAR ARRAY DEPLOYMENT MECHANISM **c18**
James W. Kellogg *In* NASA. Ames Research Center, The 27th Aerospace Mechanisms Symposium May 1993 p 267-282 (For primary document see N94-29627 08-15)
Avail: CASI HC A03/MF A03

The SAMPEX spacecraft, successfully launched in July 1992, carried a yo-yo despin system and deployable solar arrays. The despin and solar array mechanisms formed an integral system as the yo-yo cables held the solar array release mechanism in place. The SAMPEX design philosophy was to minimize size and weight through the use of a predominantly single string system. The design challenge was to build a system in a limited space, which was reliable with minimal redundancy. This paper covers the design and development of the SAMPEX yo-yo despin and solar array deployment mechanisms. The problems encountered during development and testing will also be discussed. MINIATURE LINEAR-TO-ROTARY MOTION ACTUATOR **c37**
Michael R. Sorokach, Jr. *In* NASA. Ames Research Center, The 27th Aerospace Mechanisms Symposium May 1993 p 299-314 (For primary document see N94-29627 08-15)
Avail: CASI HC A03/MF A03

A miniature hydraulic actuation system capable of converting linear actuator motion to control surface rotary motion has been designed for application to active controls on dynamic wind tunnel models. Due to space constraints and the torque requirements of an oscillating control surface at frequencies up to 50 Hertz, a new actuation system was developed to meet research objectives. This new actuation system was designed and developed to overcome the output torque limitations and fluid loss/sealing difficulties associated with an existing vane type actuator. Static control surface deflections and dynamic control surface oscillations through a given angle are provided by the actuation system. The actuator design has been incorporated into a transonic flutter model with an active trailing edge flap and two active spoilers. The model is scheduled for testing in the LaRC 16 Foot Transonic Dynamics Tunnel during Summer 1993. This paper will discuss the actuation system, its design, development difficulties, test results, and application to aerospace vehicles. Author

Avail: CASI HC A03/MF A03

New control mechanisms technologies are currently being explored to provide alternatives to hydraulic thrust vector control (TVC) actuation systems. For many years engineers have been encouraging the investigation of electromechanical actuators (EMA) to take the place of hydraulics for spacecraft control/gimballing systems. The rationale is to deliver a lighter, cleaner, safer, more easily maintained, as well as energy efficient space vehicle. In light of this continued concern to improve the TVC system, the Propulsion Laboratory at the NASA George C. Marshall Space Flight Center (MSFC) is involved in a program to develop electromechanical actuators for the purpose of testing and TVC system implementation. Through this effort, an electromechanical thrust vector control actuator has been designed and assembled. The design consists of the following major components: Two three-phase brushless dc motors, a two pass gear reduction system, and a roller screw, which converts rotational input into linear output. System control is provided by a solid-state electronic controller and power supply. A pair of resolvers and associated electronics deliver position feedback to the controller such that precise positioning is achieved. Testing and evaluation is currently in progress. Goals focus on performance comparisons between EMA's and similar hydraulic systems. Author

Ames Research Center, The 27th Aerospace Mechanisms Symposium May 1993 p 367-375 (For primary document see N94-29627 08-15)
Avail: CASI HC A02/MF A03

The SP-100 is an electrical generating nuclear power system for space operation. This paper describes the nuclear reactor control systems and the methods used to assure reliable performance for the 10-year design life. Reliable performance is achieved by redundancy and by selecting highly reliable components and design features. Reliability is quantified by analysis using established reliability data. Areas lacking reliability data are identified for development testing. A specific development test description is provided as an example to demonstrate how this process is meeting the system reliability goals. Author

A TRANSPORTRONIC SOLUTION TO THE PROBLEM OF INTERORBITAL TRANSPORTATION
William C. Brown Jul. 1992 178 p
(Contract NAS3-25066)
(NASA-CR-191152; NAS 1.26:191152; PT-7452) Avail: CASI HC A09/MF A02

An all-electronic transportation system described by the term 'transportronics' is examined as a means of solving the current problem of the high cost of transporting material from low-Earth orbit (LEO) to geostationary orbit (GEO). In this transportation system, low cost electric energy at the surface of the Earth is efficiently converted into microwave power which is then efficiently formed into a narrow beam which is kept incident upon the orbital transfer vehicles (OTV's) by electronic tracking. The incident beam is efficiently captured and converted into DC power by a device which has a very high ratio of DC power output to its mass. Because the mass of the electric thruster is also low, the resulting acceleration is unprecedented for electric-propelled vehicles. However, the performance of the system in terms of transit times from LEO to GEO is penalized by the short time of contact between the beam and the vehicle in low-Earth orbits. This makes it necessary to place the Earth based transmitters and the vehicles in the equatorial plane thus introducing many geopolitical factors. Technically, however, such a system as described in the report may out-perform any other approach to transportation in the LEO to GEO regime. The report describes and analyzes all portions of the beamed microwave power transmission system in considerable detail. An economic analysis of the operating and capital costs is made with the aid of a reference system capable of placing about 130,000 kilograms of payload into GEO each year. More mature states of the system are then examined, to a level in which 60,000 metric tons per year could be placed into GEO. Author

AN ANALYSIS OF CARRIER PHASE JITTER IN AN MPSK RECEIVER UTILIZING MAP ESTIMATION Ph.D. Thesis Semiannual Status Report, Jul. 1993 - Jan. 1994
William P. Osborne 2 May 1994 321 p
(Grant NAG5-1491)
(NASA-CR-195806; NAS 1.26:195806) Avail: CASI HC A14/MF A03

The use of 8 and 16 PSK TCM to support satellite communications in an effort to achieve more bandwidth efficiency in a power-limited channel has been proposed. This project addresses the problem of carrier phase jitter in an M-PSK receiver utilizing the high SNR approximation to the maximum aposteriori estimation of carrier phase. In particular, numerical solutions to the 8 and 16 PSK self-noise and phase detector gain in the carrier tracking loop are presented. The effect of changing SNR on the loop noise bandwidth is also discussed. These data are then used to compute variance of phase error as a function of SNR. Simulation and hardware data are used to verify these calculations. The results show that there is a threshold in the variance of phase error versus SNR curves that is a strong function of SNR and a weak function of loop bandwidth. The M-PSK variance thresholds occur at SNR's in the range of practical interest for the use of 8 and 16-PSK TCM. This suggests that phase error variance is an important consideration in the design of these systems. Author

INTEGRATED ACTIVE AND PASSIVE CONTROL DESIGN METHODOLOGY FOR THE LaRC CSI EVOLUTIONARY MODEL Final Report
Christopher T. Voth, Kenneth E. Richards, Jr., Eric Schmitz, Russel N. Gehling, and Daniel R. Morgenthaler Apr. 1994 366 p

(Contract NAS1-19371; RTOP 590-14-91-52)
(NASA-CR-4580; NAS 1.26:4580) Avail: CASI HC A16/MF A03

A general design methodology to integrate active control with passive damping was demonstrated on the NASA LaRC CSI Evolutionary Model (CEM), a ground testbed for future large, flexible spacecraft. Vibration suppression controllers designed for Line-of Sight (LOS) minimization were successfully implemented on the CEM. A frequency-shaped H2 methodology was developed, allowing the designer to specify the roll-off of the MIMO compensator. A closed loop bandwidth of 4 Hz, including the six rigid body modes and the first three dominant elastic modes of the CEM was achieved. Good agreement was demonstrated between experimental data and analytical predictions for the closed loop frequency response and random tests. Using the Modal Strain Energy (MSE) method, a passive damping treatment consisting of 60 viscoelastically damped struts was designed, fabricated and implemented on the CEM. Damping levels for the targeted modes were more than an order of magnitude larger than for the undamped structure. Using measured loss and stiffness data for the individual damped struts, analytical predictions of the damping levels were very close to the experimental values in the (1-10) Hz frequency range where the open loop model matched the experimental data. An integrated active/passive controller was successfully implemented on the CEM and was evaluated against an active-only controller. A two-fold increase in the effective control bandwidth and further reductions of 30 percent to 50 percent in the LOS RMS outputs were achieved compared to an active-only controller. Superior performance was also obtained compared to a High-Authority/Low-Authority (HAC/LAC) controller. Author (revised)

BAG: A CODE FOR PREDICTING THE PERFORMANCE OF A GAS BAG IMPACT ATTENUATION SYSTEM FOR THE PATHFINDER LANDER
J. K. Cole and D. E. Waye Nov. 1993 57 p
(Contract DE-AC04-94AL-85000)
(DE94-003688; SAND-93-2133) Avail: CASI HC A04/MF A01

The National Aeronautics and Space Administration (NASA) is planning to launch a network of scientific probes to Mars beginning in late 1996. The precursor to this network will be PATHFINDER. Decelerating PATHFINDER from the high speed of its approach to Mars will require the use of several deceleration techniques working in series. The Jet Propulsion Laboratory (JPL) has proposed that gas bags be used to cushion the payload's ground impact on Mars. This report presents the computer code, BAG, which has been developed to calculate the pneumatic performance of gas bag impact attenuators and the one-dimensional rigid-body dynamic performance of a payload during ground impact. Electrical wires are considered as EEE parts and are covered within the ESA SCC specification series (ESA SCC 3901/XXX). This specification defines the principal properties of the wires including insulation/lay-up and electrical properties. Some additional space related materials requirements are also included, requirements such as outgassing and silver plating thickness. If a project has additional materials requirements over and above those covered by the relevant SCC specification, then additional testing is required. This is especially true for crewed spacecraft. The following topics are discussed in this context: additional requirements for manned spacecraft; flammability; arc tracking; thermal decomposition; microbial surface growth; and ageing. A NEW TEST METHOD FOR THE ASSESSMENT OF THE ARC TRACKING PROPERTIES OF WIRE INSULATION IN AIR, OXYGEN ENRICHED ATMOSPHERES AND VACUUM **c33**
Dieter Koenig *In* NASA. Lewis Research Center, Second NASA Workshop on Wiring for Space Applications Jan. 1994 p 173-188 (For primary document see N94-28697 08-18)
Avail: CASI HC A03/MF A03; 8 functional color pages

Development of a new test method suitable for the assessment of the resistance of aerospace cables to arc tracking for different specific environmental and network conditions of spacecraft is given in view-graph format. The equipment can be easily adapted for tests at different realistic electrical network conditions incorporating circuit protection and the test system works equally well whatever the test atmosphere. Test results confirm that pure Kapton insulated wire has bad arcing characteristics and ETFE insulated wire is considerably better in air. For certain wires, arc tracking effects are increased at higher oxygen concentrations and significantly increased under vacuum. All tests on different cable insulation materials and in different environments, including enriched oxygen atmospheres, resulted in a more or less rapid extinguishing of all high temperature effects at the beginning of the post-test phase. In no case was a self-maintained fire initiated by the arc. CASI

HYPERVELOCITY IMPACT INDUCED ARCING AND KAPTON PYROLIZATION IN A PLASMA ENVIRONMENT
Robert J. Christie (Rockwell International Corp., Cleveland, OH.), Steve R. Best (Auburn Univ., AL.), and Craig A. Myhre Mar. 1994 7 p
(RTOP 474-46-10)
(NASA-TM-106528; E-8656; NAS 1.15:106528) Avail: CASI HC A02/MF A01

Tests were performed on the Space Station Freedom (SSF) solar array flat conductor circuit (FCC) to determine if hypervelocity impacts could induce pyrolization of Kapton and/or cross-conductor arcing. A sample piece of FCC was placed in a plasma environment and biased to +200 V relative to the plasma potential. The FCC was then impacted with particles in the 100 micron size range with hypervelocities of about 7 km/s. These tests were unable to induce Kapton pyrolization, cross-conductor arcing, or any other plasma interaction. Author (revised)

Solar array coupons designed for the Space Station Freedom electrical power system were subjected to hypervelocity impacts using the HYPER facility in the Space Power Institute at Auburn University and the Meteoroid/Orbital Debris Simulation Facility in the Materials and Processes Laboratory at the NASA Marshall Space Flight Center. At Auburn, the solar cells and array blanket materials received several hundred impacts from particles in the micron to 100 micron range with velocities typically ranging from 4.5 to 10.5 km/s. This fluence of particles greatly exceeds what the actual components will experience in low earth orbit. These impacts damaged less than one percent of total area of the solar cells and most of the damage was limited to the cover glass. There was no measurable loss of electrical performance. Impacts on the array blanket materials produced even less damage and the blanket materials proved to be an effective shield for the back surface of the solar cells. Using the light gas gun at MSFC, one cell of a four cell coupon was impacted by a 1/4 inch spherical aluminum projectile with a velocity of about 7 km/s.

The impact created a neat hole about 3/8 inch in diameter. The cell and coupon were still functional after impact. Author (revised)

CRYOGENIC ON-ORBIT LIQUID DEPOT STORAGE ACQUISITION AND TRANSFER (COLD-SAT) EXPERIMENT SUBSYSTEM INSTRUMENTATION AND WIRE HARNESS DESIGN REPORT Final Report
Lawrence G. Edwards Mar. 1994 72 p
(Contract NAS3-25776; RTOP 506-48-00)
(NASA-CR-189172; E-8098; NAS 1.26:189172) Avail: CASI HC A04/MF A01

Subcritical cryogens such as liquid hydrogen (LH2) and liquid oxygen (LO2) are required for space based transportation propellant, reactant, and life support systems. Future long-duration space missions will require on-orbit systems capable of long-term cryogen storage and efficient fluid transfer capabilities. COLD-SAT, which stands for cryogenic orbiting liquid depot-storage acquisition and transfer, is a free-flying liquid hydrogen management flight experiment. Experiments to determine optimum methods of fluid storage and transfer will be performed on the COLD-SAT mission. The success of the mission is directly related to the type and accuracy of measurements made. The instrumentation and measurement techniques used are therefore critical to the success of the mission. This paper presents the results of the COLD-SAT experiment subsystem instrumentation and wire harness design effort. Candidate transducers capable of fulfilling the COLD-SAT experiment measurement requirements are identified. Signal conditioning techniques, data acquisition requirements, and measurement uncertainty analysis are presented. Electrical harnessing materials and wiring techniques for the instrumentation designed to minimize heat conduction to the cryogenic tanks and provide optimum measurement accuracy are listed. MICROVIBRATIONS ON A GEO TELECOMMUNICATION SATELLITE
J. M. Betermier (Centre National d'Etudes Spatiales, Toulouse, France.), M. C. Charmeau (Centre National d'Etudes Spatiales, Toulouse, France.), P. Rideau, and C. Garnier 1993 15 p
(Rept-932-440-101; ETN-94-95472) Avail: CASI HC A03/MF A01

Analyses carried out to assess the microvibration characteristics on a geostationary (GEO) satellite are reported. The aims of these studies were both to increase the knowledge of the levels of dynamic perturbations transmitted to the optical terminal on board the geostationary satellite, and to develop methods and tools able to deal with emerging applications such as SILEX (Semiconductor laser Intersatellite Link Experiment). The simulations and tests which were performed on the TDF1 satellite in order to characterize the microvibration levels at a simulated point of interface between TDF1 and a mounted instrument are summarized. The analysis of the complete transmission of the disturbances generated by onboard pieces of equipment such as momentum wheels and thrusters up to the instrument's line of sight is presented. A general simulation model was developed using JAMES software means to further investigate the coupled system: spacecraft and aerial part. Parameters which may affect microvibration transmission, such as unbalances, friction, gimbal configuration, were tuned and many simulations were run in order to quantify their impacts. A comparison between levels at the interface and on the instrument's line of sight was established for the main sources of disturbance. The adequacy of methods and tools developed for future applications is presented. ESA

SATELLITES: RELIABILITY AND OPERATION SECURITY [LES SATELLITES: FIABILITE ET SURETE DE FONCTIONNEMENT]
Philippe Giudicelli and Dominique Demarquilly 1993 4 p In FRENCH
(Rept-932-440-108; ETN-94-95478) Avail: CASI HC A01/MF A01

The importance of safety and reliability analysis is underlined. It is a crucial point for designing systems, such as satellites, in which neither failure repairing can be easily performed nor unoperating broken equipment can be replaced. A system's reliability and security can be assessed by computerized simulations, which also allow solution finding. The major difficulties concerning satellites is searching for errors in nonelectronic equipment. ESA

SUMMARY REPORT OF MISSION ACCELERATION MEASUREMENTS FOR SPACEHAB-01, STS-57 LAUNCHED 21 JUNE 1993
Brian Finley (Sverdrup Technology, Inc., Brook Park, OH.), Carlos Grodsinsky, and Richard DeLombard Mar. 1994 286 p Original contains color illustrations
(Contract NAS3-25266; RTOP 694-03-011)
(NASA-TM-106514; NAS 1.15:106514; MMAP-STS-57; E-8631) Avail: CASI HC A13/MF A03; 162 functional color pages

The maiden voyage of the commercial Spacehab laboratory module onboard the STS-57 mission was integrated with several accelerometer packages, one of which was the Space Acceleration Measurement System (SAMS). The June 21st 1993, launch was the seventh successful mission for the Office of Life and Microgravity Sciences and Application's (OLMSA) SAMS unit. This flight was also complemented by a second accelerometer system. The Three Dimensional Microgravity Accelerometer (3-DMA), a Code C funded acceleration measurement system, offering an on-orbit residual calibration as a reference for the unit's four triaxial accelerometers. The SAMS accelerometer unit utilized three remote triaxial sensor heads mounted on the forward Spacehab module bulkhead and on one centrally located experiment locker door. These triaxial heads had filter cut-offs set to 5, 50, and 1000 Hz. The mission also included other experiment specific accelerometer packages in various locations. Author (revised)

THE INFLUENCE OF APPENDAGE VIBRATION ON THE ATTITUDE DYNAMICS OF A DUAL-SPIN SATELLITE Ph.D. Thesis
Mark Channing Stabb 1992 124 p
Avail: Univ. Microfilms Order No. DA9306484

In order to complete mission requirements, many spacecraft must undergo a specific motion. Accurate prediction of a satellite's attitude over time can be very important to mission planners and satellite designers. This thesis develops a perturbation method which is used to obtain an approximate analytical solution to the equations of motion for a dual-spin satellite with a flexible appendage. The perturbation of the motion from the ideal rigid body case is obtained as a function of system parameters. With this result, the relationships between spacecraft attitude dynamics and values of the system parameters can be found and examined without having to know specific values for the parameters themselves. The flexible appendage is modeled as a nonlinear beam with a finite sized tip mass at the end. Previous studies have not examined a tip mass with finite dimensions in conjunction with the full nonlinear equations of motion for a three dimensional case. The work presented here allows for all of these effects to be considered. Examples for specific configurations of the spacecraft are presented showing the magnitudes of the perturbations as functions of system parameters. This allows for investigation of minima of the perturbations in the parameter space of the satellite, a useful tool for spacecraft designers. In addition, comparisons of the perturbation solution with a numerically integrated solution of the full equations of motion for specific values of the system parameters are also presented. The results show that the perturbation method is in very close agreement with the numerical solution for the specific configurations chosen. Dissert. Abstr.

HIGH-RESOLUTION ROBOT TRACKING AND DIRECTION FINDING FOR SPACE STATION ENVIRONMENT Ph.D. Thesis

Kamal Shahrabi 1993 178 p
Avail: Univ. Microfilms Order No. DA9315502

In the past few years the problem of location finding and tracking of extravehicular robots in space station environment, and the related problem of estimating the parameters of signals in noise, have attracted considerable interest. Conventional direction finding, tracking, and locating techniques such as maximum likelihood (ML) and multiple signal characterization (MUSIC) are proving inadequate to support the full and effective utilization of robotics in a space station environment. The scope of this work is to provide a new and more efficient signal processing technique for a space station robotic tracking system which overcomes existing technical limitations such as radio transmission multipath, station reflections, the number of robots, space station environment, stringent resolution requirements, and space station architecture. In general, this work contains block level design and study of a communication system for a space station involving spread spectrum and digital processing of signal techniques that achieves as space station robotic tracking implementation. This report contains an extensive analysis of the system performance from the following points of view: utilization of a chirp signal, which, in conjunction with a polling procedure, allows for individual robot identification, location and tracking; estimate the number of antennae; determine the location of the antennae on the space station; generate a detailed block diagram design; and perform an overall system analysis that considers the effects of signal multipath.

WAVE GENERATION BY CONTAMINANT IONS NEAR A LARGE SPACECRAFT Final Technical Report, 1 Oct. 1992 - 30 Nov. 1993
N. Singh 1993 59 p
(Grant NAG3-1373)
(NASA-CR-195797; NAS 1.26:195797) Avail: CASI HC A04/MF A01

Measurements from the space shuttle flights have revealed that a large spacecraft in a low earth orbit is accompanied by an extensive gas cloud which is primarily made up of water. The charge exchange between the water molecule and the ionospheric O(+) ions produces a water ion beam traversing downstream of the spacecraft. In this report we present results from a study on the generation of plasma waves by the interaction of the water ion beams with the ionospheric plasma. Since velocity distribution function is key to the understanding of the wave generation process, we have performed a test particle simulation to determine the nature of H2O(+) ions velocity distribution function. The simulations show that at the time scales shorter than the ion cyclotron period tau(sub c), the distribution function can be described by a beam. On the other hand, when the time scales are larger than tau(sub c), a ring distribution forms. A brief description of the linear instabilities driven by an ion beam streaming across a magnetic field in a plasma is presented. We have identified two types of instabilities occurring in low and high frequency bands; the low-frequency instability occurs over the frequency band from zero to about the lower hybrid frequency for a sufficiently low beam density. As the beam density increases, the linear instability occurs at decreasing frequencies below the lower-hybrid frequency. The high frequency instability occurs near the electron cyclotron frequency and its harmonics. Author (revised)

(NASA-TM-106405; E-8241; NAS 1.15:106405) Avail: CASI HC A03/MF A01

Space Station Freedom's (SSF's) electric power system (EPS) hardware and software verification is performed at all levels of integration, from components to assembly and system level tests. Careful planning is essential to ensure the EPS is tested properly on the ground prior to launch. The results of the test performed on breadboard model hardware and analyses completed to date have been evaluated and used to plan for design qualification and flight acceptance test phases. These results and plans indicate the verification program for SSF's 75-kW EPS would have been successful and completed in time to support the scheduled first element launch. Author (revised)

VULNERABILITY OF MANNED SPACECRAFT TO CREW LOSS FROM ORBITAL DEBRIS PENETRATION
J. E. Williamsen Apr. 1994 206 p
(NASA-TM-108452; NAS 1.15:108452) Avail: CASI HC A10/MF A03

Orbital debris growth threatens the survival of spacecraft systems from impact-induced failures. Whereas the probability of debris impact and spacecraft penetration may currently be calculated, another parameter of great interest to safety engineers is the probability that debris penetration will cause actual spacecraft or crew loss. Quantifying the likelihood of crew loss following a penetration allows spacecraft designers to identify those design features and crew operational protocols that offer the highest improvement in crew safety for available resources. Within this study, a manned spacecraft crew survivability (MSCSurv) computer model is developed that quantifies the conditional probability of losing one or more crew members, P(sub loss/pen), following the remote likelihood of an orbital debris penetration into an eight module space station. Contributions to P(sub loss/pen) are quantified from three significant penetration-induced hazards: pressure wall rupture (explosive decompression), fragment-induced injury, and 'slow' depressurization. Sensitivity analyses are performed using alternate assumptions for hazard-generating functions, crew vulnerability thresholds, and selected spacecraft design and crew operations parameters. These results are then used to recommend modifications to the spacecraft design and expected crew operations that quantitatively increase crew safety from orbital debris impacts. Author (revised)

SPACE DEBRIS REMOVAL USING A HIGH-POWER GROUND-BASED LASER
D. K. Monroe 1993 20 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, 22-29 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006363; SAND-93-1523C; CONF-940142-6) Avail: CASI HC A03/MF A01

The feasibility and practicality of using a ground-based laser (GBL) to remove artificial space debris is examined. Physical constraints indicate that a reactor-pumped laser (RPL) may be best suited for this mission, because of its capabilities for multimegawatt output long run-times, and near-diffraction-limited initial beams. Simulations of a laser-powered debris removal system indicate that a 5-MW RPL with a 10-meter-diameter beam director and adaptive optics capabilities can deorbit 1-kg debris from space station altitudes. Larger debris can be deorbited or transferred to safer orbits after multiple laser engagements. A ground-based laser system may be the only realistic way to access and remove some 10,000 separate objects, having velocities in the neighborhood of 7 km/sec, and being spatially distributed over some 10(exp 10) km(exp 3) of space. Tactical satellites (TacSats) are studied to determine their utility in meeting the needs of theater commanders. Six mission areas are studied: battlefield surveillance, communications, tactical missile warning and assessment, regional maritime surveillance, navigation, and weather. The synergistic role between strategic and tactical satellites is also considered. TacSat system concepts are provided in most mission areas as are means of implementing TacSat systems, including the launch and ground system segments. Issues raised in these areas are discussed. Finally, TacSat costs are discussed and the Working Group's conclusions and recommendations are provided.

COMETS (Communications and Broadcasting Engineering Test Satellite) is the research and development purpose satellite in the area of satellite communications and broadcasting technologies, to be launched in 1997 by H-2 launch vehicle. The main mission is to experimentally demonstrate and evaluate the technologies on inter-orbit communications, advanced satellite broadcasting on Ka-band and advanced mobile satellite communications on Ka-band and millimeter-wave band. The development of COMETS has been started on March 1991 as the preliminary design phase, and the preliminary design reviews of the subsystems and systems of COMETS had been held between June 1992 to April 1993, in which the feasibility of COMETS system was confirmed. This paper presents the outline of S/C (spacecraft) mission, system configuration, S/C operation plan and development plan of COMETS based on the results of the preliminary design. Author (NASDA)

The place of a Modular Attitude and Orbit Control Subsystem Test and Simulation Assembly (MACS-TSA) in the development process of the ISO (Infrared Space Observatory) and SAX (Italian X-ray Astronomy Satellite) spacecrafts is given, with emphasis on the simulation aspects. The MACS-TSA is used as checkout equipment during the integration of Attitude and Orbit Control System (AOCS) hardware and software at subsystem level. The other spacecraft subsystems are simulated, as well as their dynamic behavior in the orbital environment. A description of the components of the TSA is given. ESA

DYNAMICS AND CONTROL OF TETHERED SATELLITE SYSTEMS Ph.D. Thesis
Euisok Kim 1993 130 p
Avail: Univ. Microfilms Order No. DA9328752

The purpose of this research is to investigate the dynamics of a tethered satellite system in which the flexibility of the tether is considered and to design control laws for the deployment and retrieval of the tethered subsatellite using a method based on the Lyapunov stability theory. The dynamics of the system considered is modelled with as little simplifications and assumptions as possible to keep the problem tractable and at the same time physically realistic. Effects of geometric nonlinearity is taken into account. The hybrid governing equations are discretized by using the Galerkin's method. The flexible tether is also modelled as a series of beads which are connected in series by massless springs. Several tension and reel rate feedback control laws for deployment and retrieval are designed using Lyapunov's method when flexibility of the tether is neglected. It was found that the tension control laws designed or the simplified system can have a stabilizing effect on the vibrations of the tether. The performance of the full dynamic system with the designed control laws is investigated via simulations using both the Galerkin and bead model. At the same time, observations regarding the dynamics of the system and the validity of using the Galerkin's discretization procedure for a variable length tether are investigated. It is shown that the effects of geometric nonlinearity is significant during retrieval and that when geometric nonlinearity is included, an artificial instability is introduced into the Galerkin model causing sudden divergence of the system response during retrieval. This behavior is reproduced even for a simplified two dimensional example problem. It was found that the bead model produces a response that is physically realistic. Simulation studies using the bead model show that when reel rate control laws are used, vibrations grow to the point where the system becomes unstable. However, the tension control laws successfully retrieve the tethered subsatellite and were found to be effective in damping the elastic longitudinal vibrations in the early stages of retrieval. A nonrecursive order-N method for efficiently simulating the bead model is also introduced. The feasibility of implementing the order-N method for parallel computation is investigated using two parallel computer architectures. It was found that, due mostly to communication time, the use of the parallel computers do not offer any improvement in overall computation time. Dissert. Abstr.

Missions of Communications and Broadcasting Engineering Test Satellite (COMETS) are to develop and evaluate the new technologies in the field of Inter-orbit Satellite System (ISS), advanced Broadcasting Satellite System (BSS) and advanced Mobile Satellite System (MSS). Mission system of COMETS, presented in this report, includes an allocation of the overall function and performance to earth station, spacecraft and user terminal, an arrangement of the frequency assignment without interference between these three mission subsystems with telemetry command subsystem, and hardware integration. This report presents the outline of COMETS mission, overall system performance, function and performance requirements for each subsystem, and hardware configuration based on the results of the preliminary design. LOCAL INTERACTION CONTROL FOR SPACE CONSTRUCTION Ph.D. Thesis
Philip Graham Good 1993 167 p
Avail: Univ. Microfilms Order No. DA9320422

A control scheme for assembling flexible substructures is developed using sensors and actuators local to the interaction point and without the need to modify existing controllers on the interacting substructures. It assumes a nominal interaction controller is first developed to produce the desired performance for the interaction, then the stability of the system is addressed by the use of an auxiliary interaction controller, which is the focus of this dissertation. Two types of auxiliary interaction control were investigated: (1) the open loop mode (OLM) auxiliary interaction controller uses open loop modal information to stabilize the system and is based on the residual mode filter (RMF) scheme; and (2) the closed loop mode (CLM) auxiliary interaction controller uses closed loop modal information to stabilize the system and is based on the disturbance accommodation control (DAC) scheme. Theory is developed for the stability of each method under ideal actuator conditions and under conditions where actuator dynamics are present. Exponential stability theory is developed for the OLM and CLM methods to bound the slowest rate of decay of the closed loop systems. Implementation of the local interaction controllers is investigated on a computer model designed to simulate a simple space station to space shuttle docking maneuver. Dissert. Abstr.

In recent years, avionics systems development costs have become the driving factor in the development of space systems, military aircraft, and commercial aircraft. A method of reducing avionics development costs is to utilize state-of-the-art software application generator (autocode) tools and methods. The recent maturity of application generator technology has the potential to dramatically reduce development costs by eliminating software development steps that have historically introduced errors and the need for re-work. Application generator tools have been demonstrated to be an effective method for autocoding non-redundant, relatively low-rate input/output (I/O) applications on the Space Station Freedom (SSF) program; however, they have not been demonstrated for fault tolerant, high-rate I/O, flight critical environments. This contract will evaluate the use of application generators in these harsh environments. Using Boeing's quad-redundant avionics system controller as the target system, Space Shuttle Guidance, Navigation, and Control (GN&C) software will be autocoded, tested, and evaluated in the Johnson (Space Center) Avionics Engineering Laboratory (JAEL). The response of the autocoded system will be shown to match the response of the existing Shuttle General Purpose Computers (GPC's), thereby demonstrating the viability of using autocode techniques in the development of future avionics systems. Compatibility between an arcjet propulsion system and a communications satellite was verified by testing a Government-furnished, 1.4 kW hydrazine arcjet system with the FLTSATCOM qualification model satellite in a 9.1-meter (30-foot) diameter thermal-vacuum test chamber. Background pressure was maintained at 10(exp -5) torr during arcjet operation by cryopumping the thruster exhaust with an array of 5 K liquid helium cooled panels. Power for the arcjet system was obtained from the FLTSATCOM battery simulator. Spacecraft telemetry was monitored during each thruster firing period. No changes in telemetry data attributable to arcjet operation were detected in any of the tests. Electromagnetic compatibility data obtained included radiated emission measurements, conducted emission measurements, and cable coupling measurements. Significant noise was observed at lower frequencies. Above 500 MHz, radiated emissions were generally within limits, indicating that communication links at S-band and higher frequencies will not be affected. Other test data taken with a diagnostic array of calorimeters, radiometers, witness plates, and a residual gas analyzer evidenced compatible operation, and added to the data base for arcjet system integration. Two test series were conducted. The first series only included the arcjet and diagnostic array operating at approximately 0.1 torr background pressure. The second series added the qualification model spacecraft, a solar panel, and the helium cryopanels. Tests were conducted at 0.1 torr and 10(exp-5) torr. The arcjet thruster was canted 20 degrees relative to the solar panel axis, typical of the configuration used for stationkeeping thrusters on geosynchronous communications satellites.

This report presents the results of experimental and numerical investigations of the flow field in the head-end star grain slots of the Space Shuttle Solid Rocket Motor. This work provided the basis for the development of an improved solid rocket motor ignition transient code which is also described in this report. The correlation between the experimental and numerical results is excellent and provides a firm basis for the development of a fully three-dimensional solid rocket motor ignition transient computer code. (NASA-TM-106406; E-8242; NAS 1.15:106406) Avail: CASI HC A03/MF A01

NASA has completed a preliminary mission and systems study of nuclear electric propulsion (NEP) systems for 'split-sprint' human exploration and related robotic cargo missions to Mars. This paper describes the study, the mission architecture selected, the NEP system and technology development needs, proposed development schedules, and estimated development costs. Since current administration policy makers have delayed funding for key technology development activities that could make Mars exploration missions a reality in the near future, NASA will have time to evaluate various alternate mission options, and it appears prudent to ensure that Mars mission plans focus on astronaut and mission safety, while reducing costs to acceptable levels. The split-sprint nuclear electric propulsion system offers trip times comparable to nuclear thermal propulsion (NTP) systems, while providing mission abort opportunities that are not possible with 'reference' mission architectures. Thus, NEP systems offer short transit times for the astronauts, reducing the exposure of the crew to intergalactic cosmic radiation. The high specific impulse of the NEP system, which leads to very low propellant requirements, results in significantly lower 'initial mass in low earth orbit' (IMLEO). Launch vehicle packaging studies show that the NEP system can be launched, assembled, and deployed, with about one less 240-metric-ton heavy lift launch vehicle (HLLV) per mission opportunity - a very Technology development cost of the nuclear reactor for an NEP system would be shared with the proposed nuclear surface power systems, since nuclear systems will be required to provide substantial electrical power on the surface of Mars. The NEP development project plan proposed includes evolutionary technology development for nuclear electric propulsion systems that expands upon SP-100 (Space Power - 100 kw(e)) technology that has been developed for lunar and Mars surface nuclear power, and small NEP systems for interplanetary probes. System upgrades are expected to evolve that will result in even shorter trip times, improved payload capabilities, and enhanced safety and reliability. Author

Haynes 188, a cobalt-based superalloy, will be used to make thermal energy storage (TES) containment canisters for a 2 kW solar dynamic ground test demonstrator (SD GTD). Haynes 188 containment canisters with a high thermal emittance (epsilon) are desired for radiating heat away from local hot spots, improving the heating distribution, which will in turn improve canister service life. In addition to needing a high emittance, the surface needs to be durable in an elevated temperature, high vacuum environment for an extended time period. Thirty-five Haynes 188 samples were exposed to 14 different types of surface modification techniques for emittance and vacuum heat treatment (VHT) durability enhancement evaluation. Optical properties were obtained for the modified surfaces. Emittance enhanced samples were exposed to VHT for up to 2692 hours at 827 C and less than or equal to 10(exp -6) torr with integral thermal cycling. Optical properties were taken intermittently during exposure, and after final VHT exposure. The various surface modification treatments increased the emittance of pristine Haynes 188 from 0.11 up to 0.86. Seven different surface modification techniques were found to provide surfaces which met the SD GTD receiver VHT durability requirement. Of the 7 surface treatments, 2 were found to display excellent VHT durability: an alumina based (AB) coating and a zirconia based coating. The alumina based coating was chosen for the epsilon enhancement surface modification technique for the SD GTD receiver. Details of the performance and vacuum heat treatment durability of this coating and other Haynes 188 emittance surface modification techniques are discussed. Technology from this program will lead to successful demonstration of solar dynamic power for space applications, and has potential for application in other systems requiring high emittance surfaces. LOW EARTH ORBIT DURABILITY EVALUATION OF PROTECTED SILICONE FOR ADVANCED REFRACTIVE PHOTOVOLTAIC CONCENTRATOR ARRAYS
Kim K. deGroh and Timothy A. McCollum Apr. 1994 13 p Presented at the AIAA 32nd Aerospace Sciences Meeting and Exhibit, Reno, NV, 10-13 Jan. 1994; sponsored by AIAA
(RTOP 506-41-11)
(NASA-TM-106543; E-8687; NAS 1.15:106543; AIAA Paper 94-0374)
Avail: CASI HC A03/MF A01

The need for efficient, cost effective sources of electrical power in space has led to the development of photovoltaic power systems which make use of novel refractive solar concentrators. These concentrators have been conceived in both point-focus and linear-focus designs. Current concentrator lenses are fabricated from flexible silicones with Fresnel facets along their inside surface. To insure the efficient operation of these power systems, the concentrator lenses must be durable and the silicone material must remain specularly transmitting over a reasonable lifetime in low Earth orbit (LEO) and other space environments. Because of the vulnerability of silicones to atomic oxygen and ultraviolet radiation in LEO these lenses have been coated with a multi-layer metal oxide protective coating. The objective of this research was to evaluate the LEO durability of the multilayer coated silicone for advanced refractive photovoltaic concentrator arrays with respect to optical properties and microstructure. Flat metal oxide coated silicone samples were exposed to ground-laboratory and in-space atomic oxygen for durability evaluation. Author

EVALUATION OF OXIDE-COATED IRIDIUM-RHENIUM CHAMBERS
Brian D. Reed Mar. 1994 15 p Presented at the 1993 JANNAF Propulsion Meeting, Monterey, CA, 15-19 Nov. 1993; sponsored by the JANNAF Interagency Propulsion Committee
(RTOP 506-42-31)
(NASA-TM-106442; E-8286; NAS 1.15:106442) Avail: CASI HC A03/MF A01

Iridium-coated rhenium (Ir-Re) provides long life operation of radiation-cooled rockets at temperatures up to 2200 C. Ceramic oxide coatings could be used to increase Ir-Re rocket lifetimes and allow operation in highly oxidizing environments. Ceramic oxide coatings promise to serve as both thermal and diffusion barriers for the iridium layer. Seven ceramic oxide-coated Ir-Re, 22-N rocket chambers were tested with gaseous hydrogen/gaseous oxygen (GHz/G02) propellants. Five chambers had thick (over 10 mils), monolithic coatings of either hafnia (HfO2) or zirconia (ZrO2). Two chambers had coatings with thicknesses less than 5 mils. One of these chambers had a thin-walled coating of ZrO2 infiltrated with sol gel HfO2. The other chamber had a coating composed of an Ir-oxide composite. The purpose of this test program was to assess the ability of the oxide coatings to withstand the thermal shock of combustion initiation, adhere under repeated thermal cycling, and operate in aggressively oxidizing environments. All of the coatings survived the thermal shock of combustion and demonstrated operation at mixture ratios up to 11. Testing the Ir-oxide composite-coated chamber included over 29 min at mixture ratio 16. The thicker walled coatings provided the larger temperature drops across the oxide layer (up to 570 C), but were susceptible to macrocracking and eventual chipping at a stress concentrator. The cracks apparently resealed during firing, under compression of the oxide layer. The thinner walled coatings did not experience the macrocracking and chipping of the chambers that was seen with the thick, monolithic coatings. However, burn-throughs in the throat region did occur in both of the thin-walled chambers at mixture ratios well above stoichiometric. The burn-throughs were probably the result of oxygen diffusion through the oxide coating that allowed the underlying Ir and Re layers to be oxidized. The results of this test program indicated that the thin-walled oxide coatings are better suited for repeated

thermal cycling than the thick-walled coating, while thicker coatings may be required for operation in aggressively oxidizing environments. Author

ORBITAL APPLICATIONS OF ELECTRODYNAMIC PROPULSION M.S. Thesis

Troy Irwin Dec. 1993 125 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A275413; AFIT/GA/ENY/93D-4) Avail: CASI HC A06

Electrodynamic propulsion (EDP) uses forces resulting from electric currents in conductors as a spacecraft travels through a magnetic field. A vehicle-independent expression for the specific power required for any maneuver is derived and used to assess EDP feasibility. Analytical expressions for the accelerations and combined current-conductor vector required to change the orbital plane or the argument of perigee are developed based on Lagrange's planetary equations. Solutions to the forced Clohessy-Wiltshire equations are developed to study iii-plane rendezvous. Results show EDP can change inclination or right ascension of the ascending mode at approximately 0.4 degrees/day with current spacecraft specific power technology. The effects of the Earth's oblateness on a 24 hour, 90 degree inclination Molniya orbit can be negated. Rendezvous is possible with EDP, and approaches along the target velocity vector with no attitude change are possible with current spacecraft specific power. Approaches involving altitude changes will be possible when modest spacecraft power improvements are made. EDP allows a soft dock - velocities and accelerations decay to zero as the chase vehicle the target - and there is no thruster plume to impart momentum or contaminate the target. DTIC

ROCKET ENGINE SYSTEM RELIABILITY ANALYSES USING PROBABILISTIC AND FUZZY LOGIC TECHNIQUES

Terry L. Hardy and Douglas C. Rapp Apr. 1994 18 p Proposed for presentation at the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; sponsored by the AIAA, ASME, SAE, and ASEE

(RTOP 506-42-72)

(NASA-TM-106519; E-8640; NAS 1.15:106519; AIAA Paper 94-2750) Avail: CASI HC A03/MF A01

The reliability of rocket engine systems was analyzed by using probabilistic and fuzzy logic techniques. Fault trees were developed for integrated modular engine (IME) and discrete engine systems, and then were used with the two techniques to quantify reliability. The IRRAS (Integrated Reliability and Risk Analysis System) computer code, developed for the U.S. Nuclear Regulatory Commission, was used for the probabilistic analyses, and FUZZYFTA (Fuzzy Fault Tree Analysis), a code developed at NASA Lewis Research Center, was used for the fuzzy logic analyses. Although both techniques provided estimates of the reliability of the IME and discrete systems, probabilistic techniques emphasized uncertainty resulting from randomness in the system whereas fuzzy logic techniques emphasized uncertainty resulting from vagueness in the system. Because uncertainty can have both random and vague components, both techniques were found to be useful tools in the analysis of rocket engine system reliability. Author (revised)

NON-ISOLATED 30 kW CLASS ARCJET PCU Final Report

See-Pok Wong and Edward J. Britt Mar. 1994 40 p

(Contract NAS3-25609; RTOP 506-42-31)

(NASA-CR-189148; E-7426; NAS 1.26:189148; SPI-39-10) Avail: CASI HC A03/MF A01

A 30 kW class arcjet Power Conditioning Unit, PCU, was built and tested during this Phase 2 SBIR contract. The PCU is an improved version of two previously developed PCU's. All of these units are 3-phase, 20 kHz buck regulators with current mode feed back to modulate the duty cycle to control the arcjet current at any selected operating point. The steady state control can assure arcjet stability despite the negative dynamic resistance of the arc discharge. The system also has a circuit to produce a high voltage start pulse to breakdown the gas and initiate the arc. The start pulse is formed by temporarily switching a short current path across the output terminals with a special solid state switching array. The switches then open rapidly, and the energy stored in the output inductors of the buck regulator produces a pulse of approximately 2500 V for approximately 500 nsec. The system was tested and modified until the transition to steady operation occurred after start up with a very small surge current overshoot. The system also can withstand a direct short circuit across the output without damage. The automatic feed back control simply reduces the duty cycle to hold the current at the set point. When the short is removed the full power output is immediately restored. This latest version arcjet PCU is conduction cooled to remove waste heat by conduction to the base plate. This unit is closer to flight a type of design than the previous functional bread boards. Waste heat is small because the PCU has a very high efficiency, 296 percent. The PCU was extensively tested with resistor loads to simulate operation with an arcjet. The unit was tested with ammonia arcjets at the Jet Propulsion Laboratory. Approximately 400 hours of testing were completed, with several starts. Many hours were also demonstrated with resistive loads. Some testing with hydrogen arcjets was also carried out at NASA LeRC. This system concept is now the design base for the ATTD program. Author (revised)

A VARIABLE SELECTION HEURISTIC FOR SOLID ROCKET MOTOR DESIGN Ph.D. Thesis

J. Wayne McCain 1993 202 p

Avail: Univ. Microfilms Order No. DA9324488

This dissertation research enhances an existing solid rocket motor design code by implementing an independent variable selection heuristic to precede the code's pattern search optimizer. The heuristic analyzes the effect of altering each independent SRM design variable and selects, by comparing calculated partial derivatives with an experimental threshold value, the parameters to be varied during design. By employing the heuristic, subjectivity is reduced, the design process is more efficient, and the risk of selecting a 'local optimum' is mitigated. Use of the new code's heuristic is illustrated with six test cases. The Fortran source code is listed in an appendix. Dissert. Abstr.

DEVELOPMENT AND VERIFICATION OF A MODEL TO PREDICT IMPINGEMENT CURRENTS FOR ION THRUSTERS

Jeffery Monheiser Apr. 1994 101 p

(Grant NAG3-1206)

(NASA-CR-195322; E-8756; NAS 1.26:195322) Avail: CASI HC A06/MF A02

A One Dimensional model describing the production of ions that impinge on accelerator grids and cause them to erode is developed. Experimental data are obtained that show measured impingement currents agree with currents computed using this model to within +/- 30 percent. Data are also presented which show that impingement current ions are produced by charge exchange rather than single or multistep electron-impact reactions. Electrical potentials measured in the regions adjacent to and downstream of an accelerator grid are presented to show that charge exchange ions that impinge on the grid can be conveniently separated into two groups, one created upstream and the second created downstream of an ion beam neutralization boundary. All of the ions created in the first region impinge on accelerator grids while only a fraction of those created downstream of the neutralization boundary do. Data are also presented to show that experimentally measured values of the distance from the accelerator grid to this neutralization boundary agree with values computed using an equation developed by Kerslake. The One Dimensional model can be used to separate the relative contributions to impingement current ions produced from background atoms and atoms that come from the thruster. The model is applied to show that ions produced from xenon background atoms dominate impingement currents measured in many ground tests. Impingement currents in space should be substantially less because this contribution to the current will be negligible. Author (revised)

ASPECTS OF MODEL-BASED ROCKET ENGINE CONDITION MONITORING AND CONTROL Final Report

Gerald R. Karr and Arthur J. Helmicki Apr. 1994 33 p

(Grant NAG8-212)

(NASA-CR-195116; NAS 1.26:195116; UAH-5-30175) Avail: CASI HC A03/MF A01

A rigorous propulsion system modelling method suitable for control and condition monitoring purposes is developed. Previously developed control oriented methods yielding nominal models for gaseous medium propulsion systems are extended to include both nominal and anomalous models for liquid mediums in the following two ways. First, thermodynamic and fluid dynamic properties for liquids such as liquid hydrogen are incorporated into the governing equations. Second, anomalous conditions are captured in ways compatible with existing system theoretic design tools so that anomalous models can be constructed. Control and condition monitoring based methods are seen as an improvement over some existing modelling methods because such methods typically do not rigorously lead to low order models nor do they provide a means for capturing anomalous conditions. Applications to the nominal SSME HPFP and degraded HPFP serve to illustrate the approach. Derived from text

SPECIALIZED DATA ANALYSIS OF SSME AND ADVANCED PROPULSION SYSTEM VIBRATION MEASUREMENTS Final Report, Jun. 1989 - Oct. 1993
Thomas Coffin, Wayne L. Swanson, and Yen-Yi Jong Oct. 1993 430 p
(Contract NAS8-38156)
(NASA-CR-193940; NAS 1.26:193940; ER-60900-93-F) Avail: CASI HC A19/MF A04

The basic objectives of this contract were to perform detailed analysis and evaluation of dynamic data obtained during Space Shuttle Main Engine (SSME) test and flight operations, including analytical/statistical assessment of component dynamic performance, and to continue the development and implementation of analytical/statistical models to effectively define nominal component dynamic characteristics, detect anomalous behavior, and assess machinery operational conditions. This study was to provide timely assessment of engine component operational status, identify probable causes of malfunction, and define feasible engineering solutions. The work was performed under three broad tasks: (1) Analysis, Evaluation, and Documentation of SSME Dynamic Test Results; (2) Data Base and Analytical Model Development and Application; and (3) Development and Application of Vibration Signature Analysis Techniques. ALKYLENE-BRIDGED POLYGERM- AND POLYGERMSILSESQUI-OXANES: NEW HYBRID ORGANIC-INORGANIC MATERIALS
G. M. Jamison, D. A. Loy, G. Zender, and K. J. Shea 1993 9 p Presented at the 207th Spring National Meeting of the American Chemical Society, San Diego, CA, 13-18 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005096; SAND-93-2514C; CONF-940301-5) Avail: CASI HC A02/MF A01

Alkylene-bridge polygerm- and polygermsilsequioxanes have been formed by hydrolysis-condensation of their corresponding (EtO)(sub 3)M(CH(sub 2))(sub n)Ge(OEt)(sub 3) monomers under HCl- and NEt(sub 3)-catalyzed conditions in ethanol. Solid state (sup 13)C and (sup 29)Si NMR indicate the retention of the alkylene bridging moiety during polymerization. The resulting aerogels are mesoporous materials with high surface areas. Incorporation of the short ethylene bridging unit results in higher surface areas than when heylene bridges are present. The porous nature of hexylene-bridged hybrid network Si(CH(sub 2))(sub 6)GeO(sub 3))(sub n) appears insensitive to the acidic or basic nature of the catalyst employed in it formation, in contrast to its polysilsesquioxane counterpart. Work is underway to determine the origin of porosity in these materials, and to characterize xerogel materials generated from these monomers. DOE

FORMATION AND CHEMICAL REACTIVITY OF CARBON FIBERS PREPARED BY DEFLUORINATION OF GRAPHITE FLUORIDE
Ching-Cheh Hung Apr. 1994 29 p Presented at the 21st Biennial Conference on Carbon, Buffalo, NY, 13-18 Jun. 1993; sponsored by the American Carbon Society
(RTOP 506-41-41)
(NASA-TM-106398; E-8228; NAS 1.15:106398) Avail: CASI HC A03/MF A01

Defluorination of graphite fluoride (CFX) by heating to temperatures of 250 to 450 C in chemically reactive environments was studied. This is a new and possibly inexpensive process to produce new carbon-based materials. For example, CF 0.68 fibers, made from P-100 carbon fibers, can be defluorinated in BrH2C-CH = CH-CH2Br (1,4-dibromo-2butene) heated to 370 C, and graphitized to produce fibers with an unusually high modulus and a graphite layer structure that is healed and cross-linked. Conversely, a sulfur-doped, visibly soft carbon fiber was produced by defluorinating CF 0.9 fibers, made from P-25, in sulfur (S) vapor at 370 C and then heating to 660 C in nitrogen (N2). Furthermore, defluorination of the CF 0.68 fibers in bromine (Br2) produced fragile, structurally damaged carbon fibers. Heating these fragile fibers to 1100 C in N2 caused further structural damage, whereas heating to 150 C in bromoform (CHBr3) and then to 1100 C in N2 healed the structural defects. The defluorination product of CFX, tentatively called activated graphite, has the composition and molecular structure of graphite, but is chemically more reactive. Activated graphite is a scavenger of manganese (Mn), and can be intercalated with magnesium (Mg). Also, it can easily collect large amounts of an alloy made from copper (Cu) and type 304 stainless steel to form a composite. Finally, there are indications that activated graphite can wet metals or ceramics, thereby forming stronger composites with them than the pristine carbon fibers can form. Author

GRAPHITE INTERCALATION COMPOUNDS PREPARED FROM GRAPHITE FLUORIDE
Ching-cheh Hung Mar. 1994 15 p Presented at the 21st Biennial Conference on Carbon, Buffalo, NY, 13-18 Jun. 1993; sponsored by the American Carbon Society
(RTOP 506-41-41)
(NASA-TM-106447; E-8299; NAS 1.15:106447) Avail: CASI HC A03/MF A01

The intercalation reaction between graphite fluoride and ferric chloride was observed in the temperature range of 300 to 400 C. The graphite fluorides used for this reaction have an sp(sup 3) electronic structure and are electrical insulators. They can be made by fluoridating either carbon fibers or powder having various degrees of graphitization. Intercalation is fast and spontaneous and can occur in the presence of air. The ferric chloride does not have to be predried. The products have an sp(sup 2) electronic structure and are electrical conductors. They contain new types of graphite intercalated compounds (GIC), which are mostly first stage and have an identity period near 11.1 A. This value is different from the 9.3 A value for first-stage GIC made by direct FeCl3-graphite intercalation. The new GIC contains iron and chlorine. It also contains fluorine, in concentrations that depend on the intercalation condition. This GIC deintercalated slowly in air at room temperature, but deintercalated quickly and completely at 370 C. Deintercalation is accompanied by the formation of rust (hematite) distributed unevenly on the fiber surface. When heated to 400 C in pure N2 (99.99 vol percent), this new GIC deintercalates without losing its staging structure. However, when the GIC is heated to 800 C deintercalation is complete and accompanied by the formation of iron oxides (other than hematite), distributed evenly in or on the fiber. This iron-oxide-covered fiber may be useful in making carbon-fiber/ceramic-matrix composites with strong bonding at the fiber-ceramic interface. Author (revised)

ANALYSIS OF SELECTED MATERIALS FLOWN ON INTERIOR LOCATIONS OF THE LONG DURATION EXPOSURE FACILITY Report, Oct. 1989 - Dec. 1993
H. A. Smith, K. M. Nelson, D. Eash, and H. G. Pippin Apr. 1994 111 p
(Contracts NAS1-18224; NAS1-19247; RTOP 506-43-61-02; RTOP 233-03-02-04)
(NASA-CR-4586; NAS 1.26:4586) Avail: CASI HC A06/MF A02

This report documents the post-flight condition of selected hardware taken from interior locations on the Long Duration Exposure Facility (LDEF). This hardware was generally in excellent condition. Outgassing data is presented for heat shrink tubing and fiberglass composite shims. Variation in total mass loss (TML) values for heat shrink tubing were correlated with location. Nylon grommets were evaluated for mechanical integrity; slight embrittlement was observed for flight specimens. Multi-layer insulation blankets, wire bundles, and paints in non-exposed interior locations were all in visibly good condition. Silicon-containing contaminant films were observed on silver-coated hex nuts at the space- and Earth-end interior locations. Author

The diamine, 1,3-diamino 5-penta fluoro sulfanyl benzene (DASP), was reacted with various dianhydrides to form polyimides containing an SF5 moiety. These polyimides exhibit high glass transition temperatures, high density, low solubility, and low dielectric properties. These polymers were used to prepare semipermeable membranes, wire coatings, and films and are useful for electronic, space, and piezoelectric applications.

PROCESS MODELLING FOR MATERIALS PREPARATION EXPERIMENTS Semiannual Progress Report No. 9, 1 Aug. 1993 - 31 Jan. 1994
Franz Rosenberger and J. Iwan D. Alexander 31 Jan. 1994 7 p
(Grant NAG8-790)
(NASA-CR-195782; NAS 1.26:195782) Avail: CASI HC A02/MF A01

The main goals of the research under this grant consist of the development of mathematical tools and measurement techniques for transport properties necessary for high fidelity modelling of crystal growth from the melt and solution. Of the tasks described in detail in the original proposal, two remain to be worked on: development of a spectral code for moving boundary problems, and development of an expedient diffusivity measurement technique for concentrated and supersaturated solutions. We have focused on developing a code to solve for interface shape, heat and species transport during directional solidification. The work involved the computation of heat, mass and momentum transfer during Bridgman-Stockbarger solidification of compound semiconductors. Domain decomposition techniques and preconditioning methods were used in conjunction with Chebyshev spectral methods to accelerate convergence while retaining the high-order spectral accuracy. During the report period we have further improved our experimental setup. These improvements include: temperature control of the measurement cell to 0.1 C between 10 and 60 C; enclosure of the optical measurement path outside the ZYGO interferometer in a metal housing that is temperature controlled to the same temperature setting as the measurement cell; simultaneous dispensing and partial removal of the lower concentration (lighter) solution above the higher concentration (heavier) solution through independently motor-driven syringes; three-fold increase in data resolution by orientation of the interferometer with respect to diffusion direction; and increase of the optical path length in the solution cell to 12 mm. FILAMENT TO MANDREL GAP ANALYSIS: RESULTING GAP FROM FILAMENT WINDING OVER A CONE-CYLINDER TRANSITION MANDREL (REFERENCE NMTP NO. 93838)
P. Geraghty 27 Oct. 1993 18 p
(Contract W-7405-eng-48)
(DE94-004225; UCRL-ID-115701) Avail: CASI HC A03/MF A01

The composites industry employs a method of high speed continuous reinforcement lay-down called filament winding. This is a process where resin impregnated tows, bundles of filament, are wound over a rotating mandrel. The tows, hereafter referred to as filament, are laid down over the rotating mandrel at a prescribed wind angle. Consider a cylindrical filament winding mandrel with conical features such that the filament is tangent to both the cylinder and the cone simultaneously. A gap is formed between the points of tangency. The gap distance measured along a line normal to the filament and intersecting the mandrel's axis of rotation. The maximum distance occurs between the filament and a point on the intersection of the cylinder and the cone. The problems this paper addresses are: given a cylindrical filament winding mandrel with conical features, what is the gap size for a given wind angle?; conversely, what is the wind angle for a given gap size?; and what does the geometry need to be in the mandrel transition area between the cylinder cone such that the filament remains in contact with the mandrel at all times?. CHARACTERIZATION OF STRUCTURE AND MECHANICAL PROPERTIES OF MoSi2-SiC NANOLAYER COMPOSITES
H. Kung, T. R. Jervis, M. Nastasi, T. E. Mitchell, and J. P. Hirvonen 1993 9 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE94-004982; LA-UR-93-4274; CONF-931108-33) Avail: CASI HC A02/MF A01

A systematic study of structure-mechanical properties relation is reported for MoSi2-SiC nanolayer composites. Alternating layers of MoSi2 and SiC were synthesized by DC magnetron and RF-diode sputtering, respectively. Cross-sectional transmission electron microscopy was used to examine three distinct reactions in the specimens when exposed to different annealing conditions: crystallization and phase transformation of MoSi2, crystallization of SiC, and spheroidization of the layer structures. Nanoindentation was employed to characterize the mechanical response as a function of structural changes. As-sputtered material exhibits amorphous structures in both types of layers and has a hardness of 11 GPa and a modulus of 217 GPa. Subsequent heat treatment induces crystallization of MoSi2 to form the C40 structure at 500 C and SiC to form the alpha structure at 700 C. The crystallization process is directly responsible for hardness and modulus increase in multilayers. A hardness of 24 GPa and a modulus of 340 GPa can be achieved through crystallizing both MoSi2 and SiC layers. Annealing at 900 C for two hours causes the transformation of MoSi2 into the C11(sub b) structure, as well as spheroidization of the layering to form a nanocrystalline equiaxed microstructure. A slight degradation in hardness but not in modulus is observed accompanying the layer breakdown. DOE

FABRICATION AND TESTING OF PLASMA-SPRAY FORMED MoSi2 AND MoSi2 COMPOSITE TUBES
R. G. Castro, J. R. Hellman, A. E. Segall, and D. L. Shelleman 1993 7 p Presented at the Fall Meeting of the Materials Research Society, Boston, MA, 29 Nov. - 3 Dec. 1993

(Contract W-7405-eng-36)
(DE94-004995; LA-UR-93-4230; CONF-931108-35) Avail: CASI HC A02/MF A01

Plasma-spray forming has been used to fabricate thick-wall tubes of MoSi2 and MoSi2 containing concentric layers of Al2O3. This process is being investigated as a potential fabrication method for producing tubular components of MoSi2 and MoSi2 composites for use in high temperature fuel-burner applications. Results are reported on spray forming method used to produce various tube sizes. Room temperature strength of pure MoSi2 tubes in the as-deposited condition, and after heat treating at 1500 C for two hours in vacuum, is also reported. Strength of plasma sprayed MoSi2 tubes were measured via diametral compression of O-ring and C-ring sections in air at room temperature. Prediction of the strength distribution was based on Weibull statistical theory. DOE

SERVICE LIFE PREDICTION OF COMPOSITE STRUCTURES THROUGH FIBER TESTING M.S. Thesis
Gregory S. Morin Sep. 1993 94 p
(AD-A275661) Avail: CASI HC A05/MF A01

Increasing the severity of the stress history of a structure reduces its service life. Feasibility studies to increase the zero fuel weight of the P-3 Orion depend heavily on the resulting decrease in service life of the wing box and airframe. One option of extending the service life of existing aircraft is through the replacement or augmentation of critical structural members with composite materials. Since structural composites do not yet have adequate service life statistics, life predication must be through probability modeling. Such modeling can begin with experimental data on accelerated testing of fiber life under several sustained load levels. This data can be the basis for an appropriate strength-life model of the fiber which can in term be related to the strength-life model of the composite by the local-load sharing model. The local-load sharing model captures the physical failure sequence of fiber failure within a composite. Such a strength-life model, when combined with structural analysis, can be used to predict an airframe's service life under the changed conditions associated with the zero fuel weight increase. DTIC

SAFETY ENHANCEMENT OF COMPOSITES VIA PERIODIC PROOF TESTING M.S. Thesis
Joseph H. Woodward Sep. 1993 74 p
(AD-A275662) Avail: CASI HC A04/MF A01

The development of new composite materials, which lack the historical field data base, has led to the need for an accelerated life testing method applicable to composites. Accelerated life testing by increasing the sustained stress levels requires the modeling and validation of a strength-life relation. Proof testing of composite fibers by over-loading is one step in the understanding of the relationship. It is also important in the reliability and safety assurance in deployment of composite structures. A parametric study examined the strength-life relation of composite fibers and a methodology to analyze the fiber failures after proof testing. The fiber statistical strength was modeled by a probability of failure model while a deterministic approach was taken considering individual fibers and the associated life reduction each fiber experienced during the proof testing procedure. Also studied was the distribution of the first failure to occur after proof testing in order to understand the effects of the sustained load and the proof load on fiber life. DTIC

FATIGUE BEHAVIOR OF A CROSS-PLY CERAMIC MATRIX COMPOSITE AT ELEVATED TEMPERATURES UNDER TENSION-TENSION LOADING M.S. Thesis
Richard J. Tuznik Dec. 1993 99 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275466; AFIT/GAE/ENY/93D-28) Avail: CASI HC A05

A study was conducted which investigated the behavior of a Nicalon/calcium aluminosilicate (Nicalon/CAS) cross-ply (0/90)(sub 2S) ceramic matrix composite at elevated temperatures under tension-tension fatigue loading. Tension-tension fatigue tests were performed with a load ratio of R = 0.10 and a frequency of 10 Hertz at 700 C and 850 C. These results were compared to results from a previous study conducted at room temperature. Material behavior and damage was recorded by fatigue life curves, elastic modulus' maximum and minimum strain, acetate replication techniques, and post-mortem fractography. Analysis of these results showed identical matrix dominated damage behavior at RT and 700 C. Ultimate failure was caused by an accumulation of matrix damage, most of which occurred on the first cycle. However, at 850 C, significantly less damage occurred to the matrix and failure was fiber dominated. Fiber debonding was identified as the major damage mechanism responsible for final failure at this elevated temperature. DTIC

In an era of declining defense budgets, the North American defense industrial base faces the challenges of advancing and maintaining technological superiority with reduced government research and development funding. In response to this challenge, the North American Defense Industrial Base Organization (NADIBO) sponsored the Metal Matrix Composites (MMCs) assessment as a case study to assess the potential for emerging technologies to continue to advance and to remain viable in the current and projected economic environment. This assessment provides a methodology and framework for conducting similiar studies in the future and identifies opportunities to enhance the level of joint effort between the U.S. and Canada in creating and sustaining a viable MMC marketplace. INNOVATIVE PROCESSING OF COMPOSITES FOR ULTRA-HIGH TEMPERATURE APPLICATIONS, BOOK 1 Annual Report
Reza Abbaschian Nov. 1993 101 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-4075)
(AD-A275597) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The overall objective of this program was to provide a fundamental understanding of the processing science and technology necessary to fabricate ceramic-matrix, intermetallic-matrix, and metal-matrix composites with superior mechanical properties in high temperature and oxidizing environments. The composites are intended for use as structural materials for advanced aerospace applications at temperatures exceeding 1200 deg C (2200 deg F). In order to accomplish the program objective, interactive research groups were established in three key areas of (1) Fiber Fabrication, (2) Coatings and Infiltration, and (3) Composite Fabrication. The objective of the fiber fabrication group was to develop new fibers which have superior strength and toughness at high temperatures and in oxidizing environments. The research effort focused on the development of two types of fibers: (1) glass-free mullite-based fibers, and (2) oxygen-free silicon carbide fibers. The coatings program had two primary objectives: (1) to control the characteristics of matrix/reinforcing phase interfaces (e.g., to control chemical reactions and bonding at a matrix/fiber interface) and (2) to develop coatings that will improve the oxidation resistance of metal-matrix and intermetallic-matrix composites. Coatings methods utilized included

chemical vapor deposition, sol-gel processing, and solution coating with polymeric precursors to ceramics. DTIC

INNOVATIVE PROCESSING OF COMPOSITES FOR ULTRA-HIGH TEMPERATURE APPLICATIONS, BOOK 2 Annual Report
Reza Abbaschian Nov. 1993 154 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-4075)
(AD-A275598) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The overall objective of this program is to develop intermetallic-matrix composites for structural application above 1200 deg C. The development of intermetallic-matrix composites is motivated by their inherent useful properties such as excellent oxidation resistance, high melting points and relatively low densities. The main disadvantages of intermetallics are poor fracture toughness at ambient temperature and low creep resistance and strength at high temperatures. It is expected that their inherent advantages can be effectively utilized via artificial compositing. The approaches used are to improve fracture toughness via ductile phase toughening, and to increase the creep resistance and strength via high strength ceramic reinforcements such as SiC whiskers. Two classes of alloys have been selected for investigation: (1) molybdenum disilicide (MoSI2), and (2) Nb-based aluminides with the major focus on NbAl3. DTIC

BALLISTIC PERFORMANCE OF POLYCARBONATE/POLYESTER AND POLYCARBONATE/STYRENE- ACRYLONITRILE MICROLAYER SHEETS Final Report, Oct. 1991 - Jun. 1993
William G. Kohlman Jan. 1994 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-62786-AH-98)
(AD-A275462; Natick/TR-94/005) Avail: CASI HC A03

Extruded microlayer sheets of polycarbonate / polyester (PC/PCTG) and polycarbonate / styrene-acrylonitrile (PC/SAN) were tested for ballistic performance and chemical resistance. Composition of the microlayer sheets ranged from 60 to 100 percent polycarbonate. The number of layers in the approximately one-eighth inch thick sheets ranged from one for the blend control samples to 3713 layers in the PC/PCTG sheets. The normalized ballistic test results showed that some samples performed as well as and slightly better than injection molded polycarbonate samples. The failure mechanism was affected by the composition and the number of layers. Increasing composition of polycarbonate and number of layers decreased the percent of brittle failures. Immersion studies showed that the PC/PCTG microlayer sheets were attacked by diethylene triamine and xylene but slower than polycarbonate by itself. The diethylene triamine drop testing demonstrated that the microlayer sheets were attacked but the PC/SAN sheets showed the least effect. DTIC

PREDICTION OF STRESS-STRAIN RESPONSE OF SCS-6/TIMETAL-21S SUBJECTED TO A HYPERSONIC FLIGHT PROFILE
Massoud Mirdamadi (Analytical Services and Materials, Inc., Hampton, VA.) and W. Steven Johnson Feb. 1994 32 p
(RTOP 505-63-50-04)
(NASA-TM-109026; NAS 1.15:109026) Avail: CASI HC A03/MF A01

Thermomechanical response of a cross-ply SCS-6/Timetal-21S composite subjected to a generic hypersonic flight profile with the temperature ranging from -130 C to 816 C was evaluated experimentally and analytically. A two dimensional micromechanical anlaysis, VISCOPLY, was used to predict the stress-strain response of the laminate and of the constituents in each ply during thermomechanical loading conditions. In the analysis, the fiber was modeled as elastic with transverse orthotropic and temperature dependent properties and the matrix was modeled using a thermoviscoplastic constitutive relation. The fiber transverse modulus was reduced in the analysis to simulate fiber-matrix interface failure. Reasonable agreement was found between measured and predicted laminate stress-strain response when fiber-matrix debonding was modeled. Author

ON THE DYNAMIC MECHANICAL BEHAVIOR OF 3-D INTEGRATED FABRIC REINFORCED COMPOSITES Final Report
Frank K. Ko and Harry C. Rogers 5 Nov. 1993 120 p
(Contract DAAL03-86-G-0069)
(AD-A275424; ARO-23798.2-MS-F) Avail: CASI HC A06/MF A02

In order to elucidate the role of fiber architecture and test geometry on the impact behavior of 3-D braided composites, 3-D braided preforms having thicknesses varying form 0.3 in. to 1.0 in. were prepared for resin transfer molding with a vinylester resin system. Angle ply composites were fabricated for comparison with the 3-D composites to investigate the role of yarn interlacing in their dynamic impact response. The yarn interlacing was found to play an important role in raising the composites' ability to absorb impact energy, increasing its damage threshold and improving its damage containment. The 3-D network of fibrous reinforcement adds through-thickness strength and creates a complex path for crack growth. The superiority of the 3-D yarn interlacing was most obvious in the thicker structures where the degree of interlacing is more pronounced. During the course of this study, two non-destructive evaluation techniques (x-ray transmission and light transmission) were developed and utilized. X-ray transmission techniques were useful in detecting voids, improper wetting and fiber alignment in the as-molded composite plates. Light transmission was effective in characterizing the extent of damage by showing areas of delamination, debonding and cracking. DTIC

STATIC FRACTURE BEHAVIOR OF A CERAMIC MATRIX COMPOSITE AT ELEVATED TEMPERATURES M.S. Thesis
David M. Agins Dec. 1993 75 p
(AD-A275363; AFIT/GAE/ENY/93D-1) Avail: CASI HC A04/MF A01

This study investigated systematically the damage initiation, damage progression, and failure modes of a ceramic matrix composite, Nicalon/CAS, when loaded in tension at elevated temperatures in the presence of air. A cross-ply lay-up, (0/90)2s, was studied. The primary means of analysis were stress-strain data taken during monotonic and incremental load tests and crack density assessments. Testing was conducted at room temperature, 700 deg C, and 850 deg C. The stress-strain response was consistent for monotonic and incremental loading, except for a decrease in failure load at the elevated temperatures. Initial damage progression was also consistent, but the damage leading to failure and the final failure mode at 850 deg C were different due to the oxidation of the fibers. The oxidation created a brittle interface between the fiber and matrix, which resulted in an increase in fiber pull-out at the failure surface. DTIC

FATIGUE BEHAVIOR OF A CROSS-PLY CERAMIC MATRIX COMPOSITE UNDER STRAIN CONTROLLED TENSION-TENSION AND

TENSION-COMPRESSION LOADING M.S. Thesis
James J. Gudaitis Dec. 1993 207 p
(AD-A275374; AFIT/GAE/ENY/93D-17) Avail: CASI HC A10/MF A03

The purpose of this study was to investigate the fatigue response of a cross-ply (0/90)2s Nicalon/Calcium-Aluminosilicate (Nicalon/CAS) ceramic matrix composite at room temperature under strain controlled tension-tension and tension-compression fatigue loading. The primary objectives were to determine strain fatigue limits (fatigue life of at least 1,000,000 cycles) for both loading cases and to complete a fatigue life diagram (i.e. strain range versus fatigue life) for all tests. Failure mechanisms were also studied. The average initial modulus value for this lay-up was 120 GPa. DTIC

3-D BRAIDED, CONTINUOUS FIBER CERAMIC COMPOSITES PRODUCED BY CHEMICAL VAPOR INFILTRATION Final Report, 18 Jan. 1991 - 2 Jan. 1992
Mark D. Mello and Robert A. Florentine Dec. 1993 28 p
(Contract DAAL04-91-C-0004)
(AD-A275192; ARL-CR-111) Avail: CASI HC A03/MF A01

Continuous fiber reinforced ceramic composites were successfully fabricated by chemical vapor infiltration of silicon carbide and silicon nitride matrix materials. Fiber preforms were three dimensionally braided with Nicalon(TM) and Nextel(TM) fiber materials forming a network of through thickness fiber architectures. Three unique material compositions were produced with the objective of demonstrating the capability of braiding brittle ceramic fibers and producing quality composites structurally capable of performing in a ballistic environment. It is anticipated that the continuous fiber architecture will be a significant technical advantage towards improvements in ceramic armor applications where non-catastrophic failure and increased toughness are a concern. TEST AND ANALYSIS OF A STITCHED RFI GRAPHITE-EPOXY PANEL WITH A FUEL ACCESS DOOR
Dawn C. Jegley and W. Allen Waters, Jr. Mar. 1994 53 p
(RTOP 510-02-12-01)
(NASA-TM-108992; NAS 1.15:108992) Avail: CASI HC A04/MF A01

A stitched RFI graphite-epoxy panel with a fuel access door was analyzed using a finite element analysis and loaded to failure in compression. The panel was initially 56-inches long and 36.75-inches wide and the oval access door was 18-inches long and 15-inches wide. The panel was impact damaged with impact energy of 100 ft-lb prior to compressive loading; however, no impact damage was detectable visually or by A-scan. The panel carried a failure load of 695,000 lb and global failure strain of .00494 in/in. Analysis indicated the panel would fail due to collapse at a load of 688,100 lb. The test data indicate that the maximum strain in a region near the access door was .0096 in/in and analysis indicates a local surface strain of .010 in/in at the panel's failure load. The panel did not fail through the impact damage, but instead failed through bolt holes for attachment of the access door in a region of high strain. Author

MICROSTRUCTURE/PROPERTY RELATIONSHIPS FOR SCS6/TIMETAL 21-S COMPOSITE Annual Report, 1 Sep. 1992 - 31 Aug. 1993
Charles G. Schmidt, Takao Kobayashi, Christine H. Kanazawa, and Donald A. Shockey Oct. 1993 21 p
(Contract F49620-92-C-0063)
(AD-A275056; AFOSR-94-0034TR) Avail: CASI HC A03/MF A01

Fracture surfaces of tensile test specimens from SCS6/Timetal 21-S composites with (0)4 or (0/90)s ply sequences were examined to characterize the failure processes. Fracture surface topography analysis (FRASTA) was used to quantitatively characterize the fracture surfaces. Results indicate that the topographies of the matrix fracture surfaces are a strong function of processes that occur during the rapid reduction in load after the maximum load. Failure of the matrix in all composites occurs after the maximum load is reached and after some or all of the 0 deg fibers have failed. Only part of the matrix phase of the 90 deg plies in a (0/90)s composite contributes to the tensile strength. The interface strength between the fibers and the matrix is negligible and does not contribute significantly to the strength of the composite. DTIC

AN ANALYSIS OF THE MICROSTRUCTURE AND REINFORCEMENT DISTRIBUTION OF AN EXTRUDED PARTICLE-REINFORCED Al 6061-10 VOLUME PERCENT Al2O3 METAL MATRIX COMPOSITE M.S. Thesis
Fredric W. Longenecker Sep. 1993 81 p
(AD-A275050) Avail: CASI HC A05/MF A01

This research was performed in conjunction with funding by DURALCAN-USA through a Cooperative Research and Development Agreement (CRDA). The program seeks to improve the ductility of cast and extruded Al 6061-Al2O3 metal matrix composite (MMC) materials. Annealing stages were designed to be introduced into combined extrusion and drawing operations during the processing of the MMC's. This work has included a comprehensive analysis of a composite's microstructure as related to processing strains ranging from zero to 5.32 during extrusion/drawing operations. As the strains were increased, particle clusters present in the as-cast material were dispersed and the particle distribution became more uniform. Strains of greater than 4.0 were required in order to disperse the clusters and substantially eliminate banding of the particle distribution. The recrystallized grain size in the Al matrix decreased as increased processing strain was applied to the material. The grain size appeared to be stable and resistant to coarsening during subsequent solution heat treatment. Quantitative image analysis revealed no change in apparent particle size or aspect ratio indicating no fracturing of the particles during processing. The image analysis revealed no readily measurable feature to be used to assess uniformity of the particle distribution. DTIC

PROPERTIES OF GRAPHITE FIBER REINFORCED COPPER MATRIX COMPOSITES FOR SPACE POWER APPLICATIONS Final Report
David L. Ellis Aug. 1992 14 p
(Contract NCC3-94; RTOP 590-13-11)
(NASA-CR-191026; E-7491; NAS 1.26:191026) Avail: CASI HC A03/MF A01

The thermal and mechanical properties of pitch-based graphite fiber reinforced copper matrix (Gr/Cu) composites usable for space applications such as radiator fins were investigated. Thermal conductivity was measured as a function of fiber volume fraction and architecture. Results showed for unidirectional P-100 Gr/Cu composites, the longitudinal thermal conductivity was nearly independent of fiber volume fraction. Transverse thermal conductivities (perpendicular to the fibers) were strongly affected by the fiber volume fraction with higher volume fractions resulting in lower thermal conductivities. The effect of architecture on thermal conductivity followed the cosine squared law for simple architectures. Insufficient data are available currently to model more complex architectures, but adding fibers in the direction of the heat flow increases the thermal conductivity as low conductivity plies are supplemented by high conductivity plies. Thermal expansion tests were conducted on the Gr fibers and Gr/Cu composites. The results show a considerable thermal expansion mismatch between the fibers and the Cu matrix. The longitudinal thermal expansion showed a strong dependence on the architecture of the Gr/Cu composites. The composites also show a thermal expansion hysteresis. The hysteresis was eliminated by an engineered interface. Mechanical testing concentrated on the dynamic modulus and strength of the composites. The dynamic modulus of the Gr/Cu composites was 305 GPa up to 400 C, a value equivalent to Be. The strengths of the composites were less than expected, but this is attributed to the poor bond across the interface between the Gr fibers and Cu matrix. Testing of composites with an engineered interface is expected to yield strengths nearer the values predicted by the rule of mixtures.

CHARACTERISATION AND PROCESSING OF SiC/MAS-L GLASS CERAMIC MATRIX COMPOSITE [ELABORATION ET CARACTERISATION DU COMPOSITE A MATRICE VITROCERAMIQUE SIC/MAS-L]
G. Larnac, P. Peres, and J. M. Donzac 1993 22 p In FRENCH Submitted for publication
(Rept-932-430-111; ETN-94-95469) Avail: CASI HC A03/MF A01

Results concerning microstructural studies as well as mechanical property evaluations carried out on SiC-MAS-L composites under air and inert atmosphere as a function of temperature are presented. MAS is MgO-Al2O3-SiO2. These ceramic fiber reinforced glass-ceramic matrix composites were made by hot unidirectional pressing. Two types of thermal cycling were determined leading to different matrix microstructures. In one case, the matrix was composed of a mixture of crystalline and amorphous phases, and in the other the matrix was totally ceramicized. The mechanical characterization in an inert atmosphere as a function of temperature showed that these two matrices behaved differently. When the composite is tested in air, it produces, above 800 C, an increase in the constraint of interfacial strength and a modification of the mode of rupture. It is concluded that ceramic fiber reinforced glass-ceramic composites represent potential materials for thermomechanical applications up to 1000 C. ESA

GLASS-CERAMIC MATRIX COMPOSITES
Jean F. Jamet 1993 11 p Presented at the A.A.A.F. Conference, Bordeaux, France, 12-13 Oct. 1992
(Rept-932-430-112; ETN-94-95470) Avail: CASI HC A03/MF A01

The history of glass-ceramic matrices is given and reasons for the present interest in these materials are also given: their state of the art is considered taking into account the glass composition, glass synthesis (the melting route and the chemical route), the densification technology (hot pressing, injection molding of short fiber matrix compound, matrix transfer molding, hot isostatic pressing), and sandwich structrure feasibility. The glass-ceramic matrices were characterized taking into account their high temperature behavior, mechanical fatigue behavior, and creep behavior. Main application aims of aerospace companies with this composite are listed. ESA

ASSESSMENT OF THE FIBRE VOLUME DISTRIBUTION AROUND OPTICAL FIBRES
Klas Levin and Pavel Sindelar Jun. 1993 30 p
(Contract FMV52700-90-066-16-001)
(FFA-TN-1993-12; ETN-94-95526) Avail: CASI HC A03/MF A01

The disturbance of embedded optical fibers on fiber distribution in carbon fiber reinforced plastics is addressed. Results for a number of configurations in terms of the variation of fiber volume content around optical fibers in laminates are presented. The width of the wedge shaped matrix pocket, which occurs when the angle between the optical fiber and adjacent plies differ, was determined for different configurations. The results showed that a region with low fiber volume content appeared extending out from the optical fiber despite the same orientation of optical fiber and the surrounding carbon fibers in the adjacent plies. The size of the region was affected by the direction: namely, the region was greater in the horizontal than in vertical direction. Besides different coating materials, neither diameter of optical fiber, its location in the laminate, nor type of laminate had any significant effect on the distribution of the fiber volume content. The smallest region was detected for the polyimide coated optical fiber with the stiffest coating tested. Only the angle between the optical fiber and the adjacent carbon fiber orientation did contribute to the width of the matrix pocket. The largest matrix pockets were observed when the optical fiber was oriented perpendicular to the surrounding carbon fibers. Even for fairly large variation of the optical fiber diameters, the width of the matrix pocket was almost similar. ESA

DAMAGE MESO-MODELING OF 3D EVOLUTIVE COMPOSITES [MESO-MODELISATION DE L'ENDOMMAGEMEMT DE COMPOSITES EVOLUTIFS TRIDIRECTIONNELS]
O. Allix (Ecole Normale Superieure, Cachan, France.), C. Cluzel (Ecole Normale Superieure, Cachan, France.), P. Ladeveze (Ecole Normale Superieure, Cachan, France.), and P. Peres 1993 12 p In FRENCH Presented at the 8th Journees Nationales sur les Materiaux Composites, 16-18 Nov. 1992
(Rept-932-430-106; ETN-94-95464) Avail: CASI HC A03/MF A01

An evolutive Three Dimensional (3D) carbon-carbon composite developed for thermostructural applications is dealt with. The composite looks like a plate reinforced in the normal direction by fiber yarns in order to prevent delamination. The choice of the stacking sequence and the proportion of normal reinforcement lead to a range of materials. Two mesomodelings are proposed. In the first the composite is modeled as a stacking of damageable and slightly inelastic single layers. This enables the prediction of the inner rupture of a structure under complex loadings. This approach provides a simple tool for the optimization of the choice of a stacking sequence as regards to the inner deteriorations. Another aspect concerns the understanding of the 3D mechanisms of degradation, especially delamination in order to optimize the distribution of the normal reinforcements. This second approach is in progress and is, at present, developed in elasticity only. Asymptotic developments are used to obtain, by means of finite elements, the 3D distribution of stresses. ESA

MICROFOCUS RADIOSCOPY, A HIGH RESOLUTION MEANS OF INSPECTING COMPOSITE MATERIALS [LA RADIOSCOPIE A MICROFOYER, UN MOYEN D'INSPECTION HAUTE RESOLUTION DES MATERIAUX COMPOSITES]
Daniel Loubet 1993 5 p In FRENCH
(Rept-932-430-109; ETN-94-95467) Avail: CASI HC A01/MF A01

Several examples of the use of microfocus radioscopy in the field of aeronautics and space are given. The use of microfocus X-ray set compensates for the weak geometric resolution of classic radioscopy by magnification of the radiologic image. Enlargements in ratios of 1 to 100 or 200 do not pose any problems and defects as small as a few tens of microns will be easily detected. A digital treatment set of radioscopic images is a very important complement for this type of installation. Several examples of use in the field of aeronautics and space are given, using this installation. The examples given concern the control of the redressing of anti oxidation protection of thermostructural parts in which eventual cracks must be detected, and the control of the homogeneity of ceramic composites in which the porosity must be detected. CORRELATION BETWEEN WET AGEING, HUMIDITY ABSORPTION AND PROPERTIES ON COMPOSITE MATERIALS BASED ON DIFFERENT RESINS FAMILY
J. Cinqin and P. Abjean 1993 14 p
(Rept-932-600-107; ETN-94-95486) Avail: CASI HC A03/MF A01

The material humidity content influence on the Interlaminar Shear Stress (ILSS) and on the glass transition temperature (T(sub g)) properties is pointed out. Three composite families were investigated: Bismaleimide (BMI), cyanate, and epoxy. Experimental data on humidity absorption show that for BMI and cyanate, the data can be fitted with Fick's law to follow the humidity absorption kinetics. For expoxy, the data can be fitted with Langmuir's law. Regarding the T(sub g) values, for the epoxy, the drop of T(sub g) between the dry state and the wet state occurs during the first step of humidity absorption. For the cyanate, the drop of T(sub g) appears during the last step of humidity absorption. For the BMI, no influence of humidity content on the T(sub g) values was noticed. Concerning the ILSS, for the epoxy a linear relationship between the humidity content and the ILSS was observed. For the cyanate, no influence of the humidity content on the ILSS was noted. For the BMI, a humidity content over 0.6 results in a important decrease of the ILSS. ESA

PRELIMINARY EVALUATION OF HYBRID TITANIUM COMPOSITE LAMINATES
J. L. Miller, D. J. Progar, W. S. Johnson, and T. L. St.Clair Apr. 1994 31 p
(RTOP 505-63-50-04)
(NASA-TM-109095; NAS 1.15:109095) Avail: CASI HC A03/MF A01

In this study, the mechanical response of hybrid titanium composite laminates (HTCL) was evaluated at room and elevated temperatures. Also, the use of an elastic-plastic laminate analysis program for predicting the tensile response from constituent properties was verified. The improvement in mechanical properties achieved by the laminates was assessed by comparing the results of static strength and constant amplitude fatigue tests to those for monolithic titanium sheet. Two HTCL were fabricated with different fiber volume fractions, resin layer thicknesses, and resins. One panel was thicker and was more poorly bonded in comparison to other. Consequently, the former had a lower tensile strength, while fewer cracks grew in this panel and at a slower rate. Both panels showed an improvement in fatigue life of almost two orders of magnitude. The model predictions were also in good agreement with the experimental results for both HTCL panels. Author (revised)

INTELLIGENT MATERIAL SYSTEMS AND STRUCTURES. PART 7: DEBONDING AND PULL-OUT OF TWO OPTICAL FIBERS FROM TWO EPOXIES [INTELLIGENTA MATERIAL SYSTEM OCH STRUKTURER. DEL 7: DEBONDING OCH PULL-OUT AV TVA SLAGS OPTISKA FEBRER]
T. Karlsson Oct. 1993 21 p In SWAHILI Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0347-3694)
(PB94-137767; FOA-C-20945-8.4-Pt-7) Avail: CASI HC A03

With the pull-out method one can monitor the load during debonding and pull-out of optical fibers from plastics and probably from fiber composites. Both of the fibers used debonded between the cladding and the skin. The bond strength between them showed great local variations which might constitute a problem for their use as sensors. The fragmentation method was shown to be useless to determine the shear strength between the optical fibers and plastics as the former are too ductile. The ultimate strength of the quartz fiber deteriorated rapidly after it had been stripped of its skin. NTIS

RELIABILITY OF COMPOSITE MATERIAL STRUCTURES. APPLICATION: HIGH PRESSURE SPHERICAL CODED TANKS [FIABILITE DES STRUCTURES EN MATERIAUX COMPOSITES. APPLICATIONS: RESERVOIRS SPHERIQUES BOBINES HAUTEPRESSION]
J. Mendez 1993 8 p In FRENCH Sponsored by ESA
(Rept-932-430-103; ETN-94-95461) Avail: CASI HC A02/MF A01

Theoretical and practical analysis of the reliability of critical non electronic components of a spacecraft, of which failure would lead to the termination of a mission, are reported. Application is made to high pressure spherical coiled tanks which stock high pressure gas and release it at precise moments during a mission. The theoretical probability of structural or functional failure is made using the 'resistance-constraint' method. The practical probability of failure of a component is estimated by identifying all the potential causes of failure which may arise during manufacture, assembling, integration, use, etc. The global probability of failure is the sum of the theoretical and practical probabilities. An apparatus and method were developed for providing a uniform, consolidated, unidirectional, continuous, fiber-reinforced polymeric material. The apparatus comprises a supply means, a forming means, a shaping means, and a take-up means. The forming means further comprises a pre-melting chamber and a stationary bar assembly. The shaping means is a loaded cooled nip-roller apparatus. Forming takes place by heating a polymeric prepreg material to a temperature where the polymer becomes viscous and applying pressure gradients at separate locations along the prepreg material. Upon exiting the forming means, the polymeric prepreg material is malleable, consolidated, and flattened. Shaping takes place by passing the malleable, consolidated, flattened prepreg material through a shaped, matched groove in a loaded, cooled nip-roller apparatus to provide the final solid product. A fiber-reinforced composite composed of a BaO-Al2O3-2SiO2 (BAS) glass ceramic matrix is reinforced with CVD silicon carbide continuous fibers. A slurry of BAS glass powders is prepared and celsian seeds are added during ball melting. The slurry is cast into tapes which are cut to the proper size. Continuous CVD-SiC fibers are formed into mats of the desired size. The matrix tapes and the fiber mats are alternately stacked in the proper orientation. This tape-mat stack is warm pressed to produce a 'green' composite. The 'green' composite is then heated to an elevated temperature to burn out organic constituents. The remaining interim material is then hot pressed to form a silicon carbide fiber-reinforced celsian (BAS) glass-ceramic matrix composite which may be machined to size.

STRESS TRANSFER MECHANICS FOR MULTIPLE PERFECTLY BONDED CONCENTRIC CYLINDER MODELS OF UNIDIRECTIONAL COMPOSITES
L. N. McCartney 1993 43 p
(PB94-138633; NPL-DMM(A)-129) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

The problem of predicting the stress and displacement distributions in an assembly of perfectly bonded multiple cylinders subject to load transfer has been reduced to manipulating sets of recurrence relations that generate a set of fourth order simultaneous ordinary differential equations. Each cylinder is assumed to be a transverse isotropic solid and account is taken of the residual stresses arising from thermal expansion mismatch effects. Numerical solutions of the problem are readily obtained using a desk-top computer and experience of application of the technique to unidirectional carbon fiber epoxy composites has shown that the new technique is robust. For a unidirectional composite with fiber fractures, by representing the fibers by one set of cylinders, the matrix by another set, and surrounding effective composite material by a third set, accurate solutions for stress and displacement distributions can be found in the vicinity of a fiber fracture that agree closely with finite element solutions. The value of the stress concentration is found to be slightly higher than that predicted by local load sharing if account is taken of the axial stress gradient in the nearest neighbor fibers, and smaller if the stress concentration is based on the average axial stress in these fibers. EFFECTS OF PHYSICAL AGING ON LONG-TERM CREEP OF POLYMERS AND POLYMER MATRIX COMPOSITES
L. Catherine Brinson (Northwestern Univ., Evanston, IL.) and Thomas S. Gates Feb. 1994 34 p
(RTOP 505-63-50-04)
(NASA-TM-109081; NAS 1.15:109081) Avail: CASI HC A03/MF A01

For many polymeric materials in use below the glass transition temperature, the long term viscoelastic behavior is greatly affected by physical aging. To use polymer matrix composites as critical structural components in existing and novel technological applications, this long term behavior of the material system must be understood. Towards that end, this study applied the concepts governing the mechanics of physical aging in a consistent manner to the study of laminated composite systems. Even in fiber-dominated lay-ups the effects of physical aging are found to be important in the long-term behavior of the composite. The basic concepts describing physical aging of polymers are discussed. Several aspects of physical aging which have not been previously documented are also explored in this study, namely the effects of aging into equilibrium and a relationship to the time-temperature shift factor. The physical aging theory is then extended to develop the long-term compliance/modulus of a single lamina with varying fiber orientation. The latter is then built into classical lamination theory to predict long-time response of general oriented lamina and laminates. It is illustrated that the long term response can be counterintuitive, stressing the need for consistent modeling efforts to make long term predictions of laminates to be used in structural situations.

ACTIVE CONTROL OF DELAMINATIONS IN SMART COMPOSITE STRUCTURES Ph.D. Thesis
Lakshmana Nagesh Bab Gummadi 1992 217 p
Avail: Univ. Microfilms Order No. DA9315877

Delaminations are one of the most commonly observed defects in laminated composite structures. Presence of delaminations significantly degrade the performance of a structure. Under certain loading conditions, these delaminations may grow and the growth of such delaminations may eventually lead to catastrophic failures. In this thesis, control of growth of delaminations is studied using the concepts of smart structures. As a first step, a detailed dynamic model of a delaminated beam, is studied. Effects of the delamination on dynamic characteristics such as natural frequencies, mode shapes and dynamic response under various loading conditions are studied. It is observed that the presence of delaminations not only affect the natural frequencies but also significantly alter the mode shapes when compared with the natural frequencies and mode shapes of a perfect beam. Later, this dynamic model has been improved to study the effects of shear deformation and rotary inertia on dynamic characteristics. Elements based on first order and third order shear deformation theories that include rotary inertia effects are developed to study the dynamics of the delaminated beam. It is observed from these studies, that shear deformation effects are quite significant for small delamination sizes. Observed changes in the dynamic behavior of the delaminated beam and the perfect beam are used to detect the size and the location of the delamination. Ibrahim time domain identification technique that uses the free response data is used for identifying natural frequencies and mode shapes. From the identified natural frequencies and mode shapes, it is concluded that changes in dynamic responses of delaminated beams can be used for the detection of the size and the location of a delamination. As a next step, growth of this identified delamination is controlled by using active control techniques. Since growth of delamination is due to high interlaminar stresses, an active control scheme that reduces the high interlaminar stresses is proposed to control the growth of delamination. Fracture mechanics based total energy release rate criterion is used to characterize the growth of delamination. Robustness aspects in the design of active control schemes are discussed for a smart structure. A robust controller that reduces vibrations even when the sensors are partially debonded is designed. Mu synthesis is used for the design of robust controllers. Dissert. Abstr.

THERMODYNAMIC ANALYSIS OF CHEMICAL COMPATIBILITY OF SEVERAL COMPOUNDS WITH Fe-Cr-Al ALLOYS Final Report
Ajay K. Misra Jul. 1993 32 p
(Contract NAS3-25266; RTOP 510-01-50)
(NASA-CR-191166; E-8009; NAS 1.26:191166) Avail: CASI HC A03/MF A01

Chemical compatibility between Fe-19.8Cr-4.8Al (weight percent), which is the base composition for the commercial superalloy MA956, and several carbides, borides, nitrides, oxides, and silicides was analyzed from thermodynamic considerations. The effect of addition of minor alloying elements, such as Ti, Y, and Y2O3, to the Fe-Cr-Al alloy on chemical compatibility between the alloy and various compounds was also analyzed. Several chemically compatible compounds that can be potential reinforcement materials and/or interface coating materials for Fe-Cr-Al based composites were identified. Author (revised)

FREE EDGE AND SIZE EFFECTS ON FAILURE INITIATION AND ULTIMATE STRENGTH OF LAMINATES CONTAINING A CENTER HOLE Ph.D. Thesis
Gou-Don Chu 1992 158 p
Avail: Univ. Microfilmes Order No. DA9313967

A failure analysis method that includes free edge and size effect was proposed for failure prediction in composite laminates containing a center hole. Categorically, this failure analysis consists of three major parts. The first is the size effect on the strength of an unnotched coupon specimen under off-axis loading. The relationship between ultimate strength and volume of the specimen was established by curve fitting the experimental results. From those test results, the strength of the composite laminate with respect to the dimension of the specimen was determined. After finding the relation between size and strength, the location of the onset of failure in the hole can be determined by comparing the strength of off-axis unnotched specimens with the hoop stress around the hole. The corresponding strength in this location was defined as the initial failure strength. From the specified failure location and stress, subsequent failure progression was performed by ply-by-ply classical laminate failure analysis in addition to free edge failure analysis of the laminate at the free surface of the hole. Experiments on (0/90/(+/- 45))(sub s) and (0/90)(sub s) laminates and their off-axis specimens were Performed to verify the present method. Dissert. Abstr.

PERFORMANCE OF A HIGHER-ORDER TRIANGULAR FINITE ELEMENT FOR COMPOSITE LAMINATED STRUCTURES Ph.D. Thesis

Hao Yu 1993 144 p
Avail: Univ. Microfilms Order No. DA9322819

In general, the shear stiffness of composite materials is much lower than that of conventional engineering materials and the transverse shear deformation is not negligible in analyzing composite structures. Unfortunately, many finite elements which include transverse deformation become too stiff when dealing with thin composite laminated plates. Therefore, a new higher-order triangular finite element model with six nodes, which includes transverse shear effects and can deal with both very thin and thick composite laminated structures, is developed in this dissertation. The basic element tests for isotropic and orthotropic materials are conducted and the results are compared with the theoretical solutions. Also, several typical bending problems for composite laminated structures, such as cross-ply, angle-ply, sandwich and swept plates and cantilever laminated beams with different stack sequences, are solved using the present finite element model, and the results are compared with their corresponding exact solutions wherever possible or those of some other existing finite element models. Interlaminar shear stress calculation and comparisons for isotropic and anisotropic plates are also presented. Dissert. Abstr.

INTERFACE ENGINEERING IN ALUMINA FIBER/GLASS COMPOSITES Ph.D. Thesis
Ramanan Venkatesh 1992 274 p
Avail: Univ. Microfilms Order No. DA9313001

The goal of the present study is the development of tough alumina fiber/glass composites. Alumina and glass form a chemical bond and hence the resulting composite is brittle. SnO2 has been shown to have no solubility in alumina and very little diffusion in glass. A weakly bonded SnO2 interphase would aid in crack deflection, fiber debonding, and/or fiber pullout in alumina/SnO2/glass composites. The proposed study modifies the interface of alumina fiber/glass composites by incorporating a layer of SnO2, and characterizes the physical and mechanical properties of the resultant composites. Thermal stresses evaluated from a three-element cylindrical model showed radial tensile stress in both PRD-166/SnO2/glass and single crystal alumina Saphikon/SnO2/glass matrix composites. Even though there was weak mechanical bonding and tensile radial thermal stress at the PRD-166/SnO2 interface, the fibers could not be pushed out during a nanoindentation test. This was attributed to fiber roughness causing a compressive clamping stress at the PRD-166/SnO2 interface. PRD-166/glass matrix composites failed in a brittle manner whereas PRD-166/SnO2/glass matrix composites exhibited nonplanar failure with crack deflection and fiber bridging as the major toughening mechanisms. Saphikon/SnO2/glass matrix composites failed in a tough manner with extensive fiber pullout. This difference in the mode of failure was due to a relatively smooth Saphikon fiber. Fracture toughness of PRD-166/glass and PRD-166/SnO2/glass matrix composites measured with a chevron notch showed that the toughness of PRD-166/SnO2/glass matrix composite was higher than that of PRD-166/glass matrix composites because of crack deflection, fiber bridging, partial fiber debonding, and some fiber pullout. A judicious interplay of roughness induced radial stress and thermal stress distribution can be used to make a tough CMC. Dissert. Abstr.

FAILURE STRENGTH AND MECHANISM OF COMPOSITE LAMINATES UNDER MULTIAXIAL LOADING CONDITIONS Ph.D. Thesis
Jerry Zhiqi Wang 1993 140 p
Avail: Univ. Microfilms Order No. DA9314957

An experimental study of strength and failure behavior of orthotropic G-10 glass fiber reinforced composite laminates in an in-plane stress state was conducted. Different types of biaxial specimens and associated test fixtures were developed and employed in the study. Standard IITRI specimens were wed to determine tensile and compressive failure strengths of G-10 composite laminates in both fill and warp directions. Biaxial tension-compression (BTC) and biaxial compression-compression (BCC) flat coupon specimens with flexible end reinforcements were designed and tested to study failure behaviors and mechanisms of composite laminates under a biaxial tension-compression and biaxial compression-compression stress states. Tubular specimens loaded in axial tension, axial compression, torsion, internal pressure, and external pressure were employed to produce desired combinations of in-plane stresses and strains. Based on the biaxial failure envelopes obtained from the tests, notched BCC specimens (BCC(n)) were tested in a biaxial compression loading condition to study failure behavior of notched laminates under a biaxial stress state. Failure mechanisms of notched and unnotched composite laminates were studied based on the test data and failure surface examination. Dissert. Abstr.

FRACTURE PROCESS ZONE OF BRITTLE COMPOSITES Ph.D. Thesis
Chang-Te Yu 1992 211 p
Avail: Univ. Microfilms Order No. DA9312767

An experimental-numerical analysis was used to study the fracture process zone (FPZ) trailing the crack tip in brittle composites. Two major parts are included in this dissertation. Part 1 is a static mode 1 fracture analysis of ceramic matrix composites. Part 2 is a mixed mode 1 and mode 2 dynamic fracture analysis of concrete. In Part 1, the FPZ which trailed a stably growing crack in SiC(w)/Al2O3 ceramic matrix composite was investigated through a hybrid experimental-numerical analysis. Surface displacements on the sides of three-point bend and wedge loaded-double cantilever beam (WL-DCB) specimens with chevron notch starter cracks were measured with moire interferometry during crack growth. The three-point bend specimens were precracked by the single edge precrack bend (SEPB) method. The experimental data was then input to two and three dimensional finite element models of the three-point bend and WL-DCB specimens, respectively, to determine by an inverse analysis the crack closure stress (CCS) versus crack opening displacement (COD) relations for SiC(w)/Al2O3. Energy dissipation rates in the trailing process zone plus the matrix fracture and fiber breakage accounted for about 80 percent of the release energy rate with the remainder being dissipated through the frontal process zone. In Part 2, a hybrid experimental-numerical procedure was used to analyze rapid crack growth in an impact loaded three-point bend concrete specimen with an offset straight precrack. Two-beam dynamic moire interferometry was used to record eight sequential moire patterns of the horizontal or vertical displacements by a ultra-high speed camera with an exposure of 2 microseconds and a framing rate of 100,000 frames/sec. The fracture responses of ceramic composites and concrete were both characterized by FPZ models which are the dominant fracture energy dissipation mechanism in this type of brittle composite. Dissert. Abstr.

BRITTLE COMPOSITES MODELING: COMPARISONS WITH MoSi2/ZrO2
S. P. Chen 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE94-004978; LA-UR-93-4307; CONF-931108-43) Avail: CASI HC A02/MF A01

We have calculated the mechanical properties of brittle composites with a spring-network (SN) model. The composites that we studied involve transformation toughening effects and the accompanying micro-cracking. Our simulation results are consistent with experiments of MoSi2 toughened with ZrO2. We found that the continuum mechanics predictions on linear dependence in e(sup T) and f about the transformation toughening are correct except for some differences in the critical transformation stress dependence. By monitoring the stress changes due to the transformation and micro-cracking we are able to separate, for the first time, the contributions from these two competing effe-ts. We found that the fracture toughness due to micro-cracks accompanying the transformation is a decreasing function of f and may be negative for large f. We also found that the fracture toughness of the composites increases as the modulus, interfacial cohesion, and uniformity of particle distributions increases.

INTERLAMINAR FRACTURE ANALYSIS FOR LAMINATED COMPOSITES UNDER COMBINED LOADING Ph.D. Thesis
Jian Li 1992 146 p
Avail: Univ. Microfilms Order No. DA9315889

Two analytical models based upon a shear deformation theory and a sublaminate approach have been developed to analyze composite laminates under extension, bending, torsion and combined loading. The first model is used to predict the free edge interlaminar stresses for composite laminates under extension, bending and torsion. The interlaminar stresses are obtained in closed form. The effectiveness of this model is validated by comparisons with a benchmark elasticity solution for unidirectional and cross-ply laminates

under torsion loading. Excellent agreement is observed. Further comparisons with finite element simulation and a Lekhnitskii's stress functions approach for off-axis and angle-ply laminates under various loading conditions are performed. Good agreement with both methods are demonstrated. The second model is for the analysis of delaminated unsymmetrical laminates subjected to extension, bending, torsion and combined loading. Closed form expressions for interlaminar stresses, total strain energy release rate and strain energy release rate components are obtained. The model is applied to the prediction of the critical interfaces, in a class of unsymmetrical laminates with (-theta,(90-theta)2, -theta,(theta-90)2, theta)T lay-ups. A comparison between the critical interfaces predicted based on the peel stress distribution through the thickness and the total strain energy release rate is presented. It is shown that the critical interface predictions based on the peel stress is consistent with the total strain energy release rate approach for most of the cases considered. It is also shown that combined loading has significant effect on potential delamination sites. Free-edge delamination may reduce or increase the extension-twist coupling depending on the location and length of the delamination, and the lay-up of the laminate. Tests of both damaged and undamaged specimens showed the same trend as the analytical predictions. This indicates that free edge delamination has a significant effect on the coupling at low level of applied loads and therefore could be easily detected at an early stage. Furthermore, the influence should be considered in the design of elastically tailored composites in order to ensure their damage tolerance. Dissert. Abstr.

In this Progress Report, we describe our continuing research activities concerning the development and implementation of advanced ultrasonic nondestructive evaluation methods applied to the inspection and characterization of complex composite structures. We explore the feasibility of implementing medical linear array imaging technology as a viable ultrasonic-based nondestructive evaluation method to inspect and characterize complex materials. As an initial step toward the application of linear array imaging technology to the interrogation of a wide range of complex composite structures, we present images obtained using an unmodified medical ultrasonic imaging system of two epoxy-bonded aluminum plate specimens, each with intentionally disbonded regions. These images are compared with corresponding conventional ultrasonic contact transducer measurements in order to assess whether these images can detect disbonded regions and provide information regarding the nature of the disbonded region. We present a description of a standoff/delay fixture which has been designed, constructed, and implemented on a Hewlett-Packard SONOS 1500 medical imaging system. This standoff/delay fixture, when attached to a 7.5 MHz linear array probe, greatly enhances our ability to interrogate flat plate specimens. The final section of this Progress Report describes a woven composite plate specimen that has been specially machined to include intentional flaws. This woven composite specimen will allow us to assess the feasibility of applying linear array imaging technology to the inspection and characterization of complex textile composite materials. We anticipate the results of this on-going investigation may provide a step toward the development of a rapid, real-time, and portable method of ultrasonic inspection and characterization based on linear array technology. MULTIPLE CONCENTRIC CYLINDER MODEL (MCCM) USER'S GUIDE Final Report
Todd O. Williams and Marek-Jerzy Pindera Apr. 1994 80 p
(Contract NAS3-26571; RTOP 505-63-12)
(NASA-CR-195299; E-8689; NAS 1.26:195299) Avail: CASI HC A05/MF A01

A user's guide for the computer program mccm.f is presented. The program is based on a recently developed solution methodology for the inelastic response of an arbitrarily layered, concentric cylinder assemblage under thermomechanical loading which is used to model the axisymmetric behavior of unidirectional metal matrix composites in the presence of various microstructural details. These details include the layered morphology of certain types of ceramic fibers, as well as multiple fiber/matrix interfacial layers recently proposed as a means of reducing fabrication-induced, and in-service, residual stress. The computer code allows efficient characterization and evaluation of new fibers and/or new coating systems on existing fibers with a minimum of effort, taking into account inelastic and temperature-dependent properties and different morphologies of the fiber and the interfacial region. It also facilitates efficient design of engineered interfaces for unidirectional metal matrix composites. Author (revised)

MICROMECHANICAL ANALYSIS OF THERMO-INELASTIC MULTIPHASE SHORT-FIBER COMPOSITES Final Report
Jacob Aboudi Mar. 1994 19 p
(Grant NAG3-1377; RTOP 505-63-12)
(NASA-CR-195290; E-8650; NAS 1.26:195290) Avail: CASI HC A03/MF A01

A micromechanical formulation is presented for the prediction of the overall thermo-inelastic behavior of multiphase composites which consist of short fibers. The analysis is an extension of the generalized method of cells that was previously derived for inelastic composites with continuous fibers, and the reliability of which was critically examined in several situations. The resulting three dimensional formulation is extremely general, wherein the analysis of thermo-inelastic composites with continuous fibers as well as particulate and porous inelastic materials are merely special cases. COMPUTATIONAL SIMULATION OF COMPOSITE STRUCTURES WITH AND WITHOUT DAMAGE M.S. Thesis Final Report
Thomas F. Wilt Mar. 1994 105 p
(Grant NAG3-50; RTOP 505-63-5B)
(NASA-CR-194433; E-8240; NAS 1.26:194433) Avail: CASI HC A06/MF A02

A methodology is described which uses finite element analysis of various laminates to computationally simulate the effects of delamination damage initiation and growth on the structural behavior of laminated composite structures. The delamination area is expanded according to a set pattern. As the delamination area increases, how the structural response of the laminate changes with respect to buckling and strain energy release rate are investigated. Rules are presented for laminates of different configurations, materials and thickness. These results demonstrate that computational simulation methods can provide alternate methods to investigate the complex delamination damage mechanisms found in composite structures. Author

DELAMINATION GROWTH IN COMPOSITES UNDER CYCLIC LOADS Ph.D. Thesis
Christian Ulf Dahlen 1993 103 p
Avail: Univ. Microfilms Order No. DA9326454

A semi-empirical model was developed for estimating the growth of delaminations inside fiber reinforced organic matrix composites subjected to cyclic loads. At any point of the circumference of the delamination mode 1, mode 2, or mixed mode conditions may exist. The form of the proposed delamination growth model follows Elber's expression for the growth of a mode 1 crack in an aluminum sheet. By employing dimensional analysis, the parameters were established which are to be included in the model. The expression obtained depends on the material properties (transverse tensile ply strength, transverse tensile ply modulus, longitudinal ply shear strength, critical energy release rate) and on the energy release rate at the location under consideration. Tests were conducted with Fiberite T300/976 and IM7/977-2 graphite epoxy composites under mode 1, mode 2, and mixed mode conditions using double cantilever beam, end notched cantilever beam, and mixed mode bending test coupons subjected to both static and cyclic loads. From these tests, first, the constants needed in the model, were determined. Second, data were generated and compared

to predictions of the model, and good agreement was found between measured and predicted delamination growths. Results of the present model were also compared to data reported previously, and the model predictions agreed well with these previous data. Dissert. Abstr.

THREE-DIMENSIONAL FREE VIBRATION ANALYSIS OF THICK ARBITRARILY LAMINATED, RECTANGULAR, CYLINDRICAL AND SPHERICAL COMPOSITE PANELS Ph.D. Thesis
Kuan Hong Huang 1993 203 p
Avail: Univ. Microfilms Order No. DA9327430

A layer-wise theory was established to solve the free vibration problem of thick, arbitrarily laminated composite panels of rectangular, cylindrical, and spherical geometry. The boundary conditions at four edges of these panels can be any combination of simply supported, free clamped, and guided, and can be varied through the thickness to model the effects of three-dimensional boundary conditions. In this three dimensional semi-analytical method, the displacement field is modeled by finite element interpolation shape functions along the thickness direction and by beam function expansions in the two in-plane directions. The natural frequencies obtained show this method to be more accurate, especially for predicting higher modes, than previous models based on the first-order transverse shear deformation theory (FSDT) or the higher-order transverse shear deformation theory (HSDT). Some in-plane vibration modes which were found to be missing in previous models are obtained in the present study. The improved accuracy of the present method can be attributed partly to the three-dimensional displacement field which allows prediction of truly three-dimensional mode shapes in thick laminates, and partly, to the layer-wise displacement field which provides the ability to model more complicated layer-wise boundary conditions, as well as layer-wise continuous stiffness properties for heterogeneous laminates. Dissert. Abstr.

DAMAGE IDENTIFICATION IN COMPOSITES USING BUILT-IN PIEZOELECTRICS Ph.D. Thesis
Charles Henry Keilers, Jr. 1993 172 p
Avail: Univ. Microfilms Order No. DA9326494

An identification method was developed that uses measured responses from piezoelectrics built into laminated composite beams to detect a delamination and estimate its size and location. This development involved both experimental and analytical work. Experiments were performed using surface-mounted piezoceramics on composite beams with and without an artificial delamination. Some of these piezoceramics were used as actuators to dynamically excite specimens while others were used as sensors to measure strains. These experiments showed that a delamination changes the dynamic forced response. Therefore, when a measured response differs from an undamaged structure's baseline response, damage could exist and the identification procedure is run. The identification procedure consists of a response comparator, a damage selector and a model. The model is run repeatedly to predict the changes in response due to different possible delaminations. After each run, the damage selector chooses the next assumed delamination size and location randomly, using an approach related to simulated annealing that improves agreement between the measured and calculated responses. The response comparator then compares these two responses using a weighted quadratic objective function. When the objective function is minimized, the responses agree, and the assumed delamination dimensions are also best estimates for the actual dimensions. The technique has been estimates for the actual dimensions. The technique has been tested using measured responses and has successfully identified artificially implanted beam delaminations. Dissert. Abstr.

STANDARDISATION REQUIREMENTS FOR ULTRASONIC C-SCANNING OF POLYMER MATRIX COMPOSITES: AN INITIAL ASSESSMENT
J. L. Lesniarek-Hamid and G. D. Sims Jun. 1993 18 p Sponsored by Dept. of Trade and Industry
(ISSN 0959-2423)
(PB94-139318; NPL-DMM(A)-105; ETN-94-95830) Copyright Avail: Issuing Activity (National Physical Lab., Teddington, Middlesex TW11 0LW, England)

As part of a wider program aimed at new or improved test methods for quality control, qualification and design data purposes, an assessment was undertaken on the 'standardization' requirements for the use of the ultrasonic C scan technique for evaluating polymer matrix composites. A compilation of that assessment, which covered current practices used by industry and requirements in terms of defect detection and measurement, is reported. Calibration of the equipment, determination of porosity and detection and measurement of all types of defects are covered. The requirements for standards was investigated. The principle needs identified are for standards for calibration of the equipment and defect detection. The large majority of participants do not measure porosity using the ultrasonic C scan technique and there was not a strong requirement for standards in this area. Very few participants were aware of the requirements in the draft European standard, pr EN2565, to measure porosity using ultrasonic methods. The results of the assessment will be used to guide a research program to satisfy the identified needs. ESA

SIMULATION OF COMPOSITE MATERIAL RESPONSE UNDER DYNAMIC COMPRESSIVE LOADING
S. A. Silling and P. A. Taylor 1993 12 p Presented at the International Union of Theoretical and Applied Mechanics (IUTAM) Symposium on Computational Mechanics of Materials, Providence, RI, 15-18 Jun. 1993

(Contracts DE-AC04-94AL-85000; DE-AC04-76DP-00789)
(DE94-005272; SAND-93-1490C; CONF-9306291-1) Avail: CASI HC A03/MF A01

Realistic computer prediction of high-velocity impact and penetration events involving composite materials requires a knowledge of the material behavior under large compressive stresses at high rates of deformation. As an aid to the development of constitutive models for composites under these conditions, methods for numerical simulation of the material response at the microstructural level are being developed. At present, the study is confined to glass fiber/epoxy composites. The technique uses a numerical model of a representative sample of the microstructure with randomly distributed fibers. By subjecting the boundary of this numerical sample to prescribed loading histories, a statistical interpretation allows prediction of the global material response. Because the events at the microstructural scale involve locally large deformation, and because of the constantly changing picture with regard to contact between the fibers, the Eulerian code CTH is used for these calculations. Certain aspects of material failure can also be investigated using this approach. The method allows the mechanical behavior of composite materials to be studied with fewer assumptions about constituent behavior and morphology than typically required in analytical efforts. DOE

EFFECT OF FIBER COATING ON MECHANICAL PROPERTIES OF NICALON FIBERS AND NICALON-FIBER/SiC MATRIX COMPOSITES
J. P. Singh, D. Singh, and R. A. Lowden Dec. 1993 10 p Presented at the 18th Annual Conference on Composites and Advanced Ceramics, Cocoa Beach, FL, 9-14 Jan. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE94-005477; ANL/ET/CP-80555; CONF-940135-2) Avail: CASI HC A02

The effect of fiber-coating thickness on retained in-situ fiber strength and the resulting mechanical properties of composites was investigated. Flexure tests in a four-point-bend mode were used to evaluate ultimate strength and work-of-fracture of the composites with various fiber-coating thicknesses. Retained in-situ fiber strength in the fractured composites was evaluated by fractographic techniques. Retained in-situ fiber strength, ultimate strength, and work-of-fracture of the composites increased with increasing fiber-coating thickness, reaching a peak value at a coating thickness of approximately 0.3 microns. Further increases in coating thickness did not improve the mechanical properties of either the fibers or the composites. A direct correlation between retained in-situ fiber strength and mechanical properties of the composites suggests that retained in-situ fiber strength has a significant influence on the mechanical properties of composites. CREEP BEHAVIOR OF MoSi2-SiC COMPOSITES
D. P. Butt, S. A. Maloy, H. Kung, D. A. Korzekwa, and J. J. Petrovic 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE94-004980; LA-UR-93-4288; CONF-931108-30) Avail: CASI HC A02/MF A01

Using a cylindrical indenter, indentation creep behavior of hot pressed and HIPed MoSi2-SiC composites containing 0-40% SiC by volume, was characterized at 1000-1200C, 258-362 MPa. Addition of SiC affects the creep behavior of MoSi2 in a complex manner by pinning grain boundaries during pressing, thus leading to smaller MoSi2 grains; by obstructing or altering both dislocation motion and grain boundary sliding; and by increasing the overall yield stress of the material. Comparisons are made between indentation and compressive creep studies. It is shown that under certain conditions, compressive creep and indentation creep measurements yield comparable results after correcting for effective stresses and strain rates beneath the indenter. STUDIES ON THE OPTIMIZATION OF DEFORMATION PROCESSED METAL-METAL MATRIX COMPOSITES Ph.D. Thesis
T. W. Ellis Jan. 1994 141 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-82)
(DE94-006033; IS-T-1676) Avail: CASI HC A07

A methodology for the production of deformation processed metal-metal matrix composites from hyper-eutectic copper-chromium alloys was developed. This methodology was derived from a basic study of the precipitation phenomena in these alloys encompassing evaluation of microstructural, electrical, and mechanical properties. The methodology developed produces material with a superior combination of electrical and mechanical properties compared to those presently available in commercial alloys. New and novel alloying procedures were investigated to extend the range of production methods available for these materials. These studies focused on the use of high pressure gas atomization and the development of new containment technologies for the liquid alloy. This allowed the production of alloys with a much more refined starting microstructure and lower contamination than available by other methods. The knowledge gained in the previous studies was used to develop two completely new families of deformation processed metal-metal matrix composites. These composites are based on immissible alloys with yttrium and magnesium matrices and refractory metal reinforcement. This work extends the physical property range available in deformation processed metal-metal matrix composites. Additionally, it also represents new ways to apply these metals in engineering applications. DOE

MICROWAVE ASSISTED CHEMICAL VAPOR INFILTRATION
D. J. Devlin 1993 11 p
(Contract W-7405-eng-36)
(DE94-005005; LA-UR-93-4343) Avail: CASI HC A03/MF A01

The purpose of this program is to develop a new process for the fabrication of ceramic matrix composites by chemical vapor infiltration. This period has been devoted in part to the exploration of material systems suitable for MACVI processing. A number of potential processing schemes are possible using combinations of absorbing and transparent material as composite components. This includes the use of an absorbing preform (nicalon fiber) combined with a transparent matrix (silicon nitride). Composites 5 cm in diameter by 1 cm. thick have been fabricated to densities of 65% theoretical. Processing times for these materials are under 20 hours. Higher densities will require additional microwave power now possible with the new reactor. The most effective MACVI scheme will involve the use of a transparent fiber with an absorbing matrix. The hot spot will be initiated by appropriate treatment of the central region of the preform. To this end, alumna fibers with pretreatments to control thermal gradients has been explored. Nextel 610 fibers have been effectively pretreated carbon coating resulting in preferential heating in the interior of the preform. Possible matrix materials include siliconized silicon carbide, doped silicon carbide, alumna, and zirconia. A patent for MACVI has been issued 10/19/93. DOE

DELAMINATION OF WOVEN E-GLASS FABRIC COMPOSITES
M. L. Dunn (Colorado Univ., Boulder.), E. D. Reedy, Jr., and T. R. Guess 1993 20 p Presented at the 39th International Symposium of the Society for the Advancement of Material and Process Engineering and Exhibition, Anaheim, CA, 11-14 Apr. 1994
(Contract DE-AC04-94AL-85000)
(DE94-003227; SAND-93-1442C; CONF-940412-1) Avail: CASI HC A03/MF A01

An experimental/analytical study investigating delamination growth in E-glass fabric/polyester composites was carried out. Double cantilever beam and end-notched flexure delamination specimens were tested, and the measured data was compared to calculated results. A stacked shell finite element methodology was developed to perform the analysis. This approach breaks the composite into sublaminate shells connected by springs spanning the delamination plane. The stacked shell analyses can use either a critical stress or a critical energy release rate criterion to propagate the delamination, and both criteria are shown to yield similar predictions. Role of connecting springs, and proper choice for spring constants has also been investigated in detail. The spring constants must be chosen in a physically meaningful way to develop consistent values of energy release rate, compliance, and the stress distribution ahead of the delamination. Calculated results for the

double cantilever beam and end-notched flexure specimens are in good agreement with measured test data and continuum finite element solutions. DOE

NUMERICAL MODELING AND PREDICTION OF THE THERMOMECHANICAL BEHAVIOR OF FIBER-REINFORCED COMPOSITES Ph.D. Thesis
Panagiotis Blanas 1993 231 p
Avail: Univ. Microfilms Order No. DA9322413

This research effort investigates the behavior of continuous fiber reinforced, unidirectional composite materials under mechanical and thermal loads. A numerical procedure is developed that allows for the prediction of composite effective properties. A micromechanical approach and the finite element method of analysis are used to model and determine the composite material response under loading. The representative volume element concept along with assumptions of regular and periodic fiber distribution arrays are employed in the micromechanics problem formulation. Both square and hexagonal fiber arrays are utilized to model the microstructure of the composite material. The composite is treated as a macroscopically homogeneous, linearly elastic and transversely isotropic medium. Linear elastic behavior is also assumed for the homogeneous fiber and matrix constituent phases. The finite element method is employed in the solution of the micromechanics boundary value problem. Two and three dimensional finite element models of the representative volume element are generated. Various layouts of these models in single and multiple cell configurations are developed and utilized in the modeling and analysis of the unidirectional composite. A number of boundary conditions and load cases are also used in the analysis to determine the behavior of the composite. Displacement and stress fields produced in the composite under the various loading conditions are obtained and used in the computation of effective property values. Effective material properties are obtained for two composite material systems. Results are compared with results from micromechanics equations and experimental data. The effect of boundary conditions on predicted effective property values is also addressed and discrepancies that occur at the free boundaries of the composite are examined.

A CLASS OF INCLUSION PROBLEMS FOR THE STRENGTHENING OF BRITTLE AND DUCTILE COMPOSITES Ph.D. Thesis
Huang-Hsing Pan 1992 232 p
Avail: Univ. Microfilms Order No. DA9321318

Using Eshelby's solution of an ellipsoidal inclusion as the point of departure, a class of inhomogeneity and transformation problems for the strengthening of brittle and ductile composites are investigated in this thesis. First, the effective elastic moduli of a two-phase composite containing aligned, two dimensional, and three dimensional randomly oriented ellipsoidal inclusions are derived. The nine, five, and two independent elastic constants for these three different classes of composites are found as a function of inclusion shape and volume concentration. The moduli are found to always lie in or on the bounds of Willis and of Hashin and Shtrikman. These results are then developed into a form suitable for the elliptic cracks, and then the influence of crack density parameters on the reduction of the effective moduli of cracked bodies is brought about. The established results for the effective moduli with softer inclusions, and with elliptic cracks, are then applied to study the microcracks and inhomogeneity, as well as the transformation, toughening of brittle solids. It is found that the toughness of brittle materials (e.g. ceramics) can always be enhanced by addition of soft particles, and by the dilatational nature of the phase transformation from tetragonal to monoclinic crystal structure. In the case of microcrack toughening, the theory derived is shown to be very close to Hutchinson's modified lowest order formula. The investigation finally is directed towards the thermal stress problems in dual-phase solids during a cooling process. For a dual-phase steel, it is found that dilational tensile stress develops in the ferrite matrix during martensitic transformation. The volume of the dual-phase steel is found to decrease first during cooling, but increase upon the occurrence of phase transformation. The thermal stress analysis is finally studied for the two-phase metal-matrix composites. An exact, local theory is derived to determine the extent of thermal stress in the inclusions and the ductile matrix for both particle and fiber-reinforced composites. For a two-phase composite containing aligned spheroidal inclusions, an energy approach is developed at the end. It is demonstrated that the thermal stress in the ductile matrix can be significantly relieved by its plastic flow.

A variety of silyl- and alkyl-germylene precursors have been synthesized and subsequently pyrolyzed in the gas phase. Arrhenius parameters were obtained employing a pulsed-stirred flow reactor for these unimolecular decompositions. These precursors are divided into two major categories by mechanism of germylene extrusion: (alpha)-elimination precursors and germylacetylenes. The extrusion of germylenes from germylacetylene precursors is of primary interest. A mechanism is proposed employing a germacyclopropene intermediate. Evidence supporting this mechanism is presented. In the process of exploring germylacetylenes as germylene precursors, an apparent dyatropic rearrangement between germanium and silicon was observed. This rearrangement was subsequently explored. DOE

The solubility of Nd(III) has been measured in a synthetic brine at pcH 6.4, 8.4, 10.4 and 12.4. The brine consisted predominantly of (Na+K)Cl and MgCl2, with an ionic strength of 7.8M (9.4m). The experimental solubility is much less than that estimated from modeling of the species in solution in equilibrium with the Nd solid using S.I.T. The predominant solid compound of Nd (III) at each pcH was determined from X-ray diffraction patterns. DOE

Coal has been known to consist of solvent soluble 'mobile phase' and solvent insoluble 'immobile phase'. This concept, which is called two phase model, is based on the idea that coal is a three dimensionally cross-linked macromolecular network. Molecular structure of coal and various coal conversion reactions have been discussed using this model. Recently, a high performance solvent system is found to solubilize coal much higher than conventional solvents. A new coal structure model other than two phase model is proposed. This report reviews recent studies on high performance solvents and new concepts of structural model of coal derived from the solvent extraction experiments. Author (NASDA)

The first evidence of biosolubilization or biodegradation of brown coal using wood-decaying fungi prompted the identification of other organisms capable of growing on and solubilizing coal. The isolation of extracellular lignin peroxidase from white-rot fungi also accelerated the enzymatic degradation study of coal. The bacterial processing revealed the effects of alkaline substances and chelator in addition to enzymatic action on coal solubilization. However, the characterization of solubilized products, attributed to high molecular weight aromatic carboxylate, raised the question about the practical application of such aerobic biological treatments which are unable to improve quality as alternative fuels and chemicals. On the other hand, recent reports suggest that coal is degraded by anaerobic microorganisms and hydrogenase/cytochrome c without an increase in oxygen and a decrease in carbon content. These results may offer a promising approach to feasible bioprocessing of coal. Author (NASDA)

Avail: CASI HC A02/MF A01

Solid state C-13 NMR (Nuclear Magnetic Resonance) spectra of carbonized and oxidized coal were measured to investigate the structural changes during carbonization and oxidation. By oxidation, coal produces gas mainly by oxidation of aliphatic chain and fraction of the aromatic carbon (fa) increased. By carbonization, all coal showed little structural changes lower than 350 C and significant changes from 350 to approximately 450 C. Aromatic carbons of all coal apparently remained in coke or char and were condensed while aliphatic carbons were decomposed to produce

tar and gas. All samples showed the same structural changes during carbonization but the degrees of the changes differed greatly according to the coal species and lower rank coal showed a much bigger change. The rate of chemical structural change during this temperature range seems to decide each coal's reactivity. Author (NASDA)

METHANOL-MEDIATED CONTINUOUS EXTRACTION OF PHENOLIC COMPOUNDS FROM COAL LIQUID [METANORU O BAITAI TO SURU SEKITAN EKIKAYUCHU NO FENORURUI NO RENZOKU CHUSHUTSU]

Yoichi Kodera, Akimitsu Matsumura, and Koji Ukegawa *In its* Journal of NIRE, Vol. 2, No. 2 25 Mar. 1993 p 27-32 In JAPANESE (For primary document see N94-28675 08-25)

Avail: CASI HC A02/MF A01

A methanol-mediated extraction method was utilized in the separation of phenolic compounds from coal liquids. A naphtha distillate of Wandoan coal liquid was treated in a continuous extraction apparatus. Flow rates of the feed oil, methanol, and water were 0.25 - 1.0, 0.125 - 0.5, and 0.125 - 0.5 L/h, respectively. Run times were three to 10 hours. The effect of varied methanol-to-oil weight ratio on extraction yields of phenolic compounds was examined. As in corresponding batch experiments, extraction yields of phenol, o-, m-, and p-cresol increased as the amount of methanol increased. However, increased addition of water reduced the yields of phenolic compounds. Removal of methanol under reduced pressure caused an oily mixture of phenolic compounds to separate from the extract. The amount of separated oil was dependent on MeOH/water, weight ratio.

PROPERTIES OF ADSORBENTS FOR COLLECTION AND ANALYSIS OF TRACE AMOUNT OF CHLOROFLUOROCARBONS IN AIR [TAIKICHU NO BIRYO CFC RUI SOKUTEI NO TAME NO HOSHUYO KYUCHAKUZAI NO KENTO]

Toshiyuki Tanaka and Heita Murakoshi *In its* Journal of NIRE, Vol. 2, No. 2 25 Mar. 1993 p 33-40 In JAPANESE (For primary document see N94-28675 08-25)

Avail: CASI HC A02/MF A01

Adsorption and desorption properties of adsorbents are investigated for measuring trace amounts of CFC (chlorofluorocarbons) in the air. Micropore structures and the breakthrough volume are measured for Tenax GC, Tenax TA, Tenax GR, Carbotrap, Carbotrap C, Carboxen 563, Carboxen 564, and Controlled-pore glass. Tenax GC was inadequate for collecting ambient chlorofluorocarbons quantitatively, and other Tenax type adsorbents are almost the same as regards their properties. Carboxen 563 and 564 showed an adequate capacity for the sampling of chlorofluorocarbons in air. However, these absorbents need a desorption temperature higher than 300 C, and produce ghost peaks and/or broad peaks during gas chromatographic analysis. Author (NASDA)

AB INITIO STUDY OF VIBRATIONAL FREQUENCY SHIFT UPON THE 1:1 ACETONE-IODINE COMPLEX FORMATION [ASETON-YOSO SAKUTAI NO SHINDOSU SHIFUTO NI KANSURU RIRONTEKI KENTO]

Osamu Setokuchi and Masaru Sato *In its* Journal of NIRE, Vol. 2, No. 2 25 Mar. 1993 p 41-50 In JAPANESE (For primary document see N94-28675 08-25)

Avail: CASI HC A02/MF A01

Vibrational frequency shift upon the 1 : 1 acetone-iodine complex formation was determined from geometries optimized at the SCF (Self Consistent Field) and MP2 (Moeller-Plesset Second Order Perturbation) levels using the ab initio MO (Molecular Orbital) theory, and comparison was made with experimental results. The SCF calculation with DZ (Double Zeta) basis sets augmented by a single set of d polarization functions gave values consistent with experimental results. The MP2 calculation failed to indicate even the sign of the shift, when using DZ basis sets without d polarization functions. Also, the shift of the nu(sub 19) acetone vibrational band was over estimated. These results are discussed from structural and energetical points of view. The origin of vibrational frequency shift is explained as being due to the behavior of orbital electrons, based on the natural bond orbital theory. Author (NASDA)

A NOVEL SPECTROSCOPIC MEASUREMENT METHOD OF RF PLASMA FOR TEMPERATURE AND ELECTRON DENSITY DIAGNOSES [KOSHUHA NETSU PURAZUMA NO ONDO-DENSHI MITSUDO BUNPU NO SOKUTEI NO TAME NO BUNKO KEISOKU SHUHO NO KENTO]

Nobuyuki Kikukawa, Masami Sugasawa, and Masakazu Nakamura *In its* Journal of NIRE, Vol. 2, No. 2 25 Mar. 1993 p 51-59 In JAPANESE (For primary document see N94-28675 08-25)

Avail: CASI HC A02/MF A01

A new scanning method for spectroscopic data acquisition of RF (Radio Frequency) plasma suitable for Abel inversion was proposed. A small telescope was mounted on a theta-stage outside the 'shield box', with only the front end being inserted through a minimum opening in the shield box. Therefore, more than several tens of spectroscopic data points required for Abel inversion can be quickly measured with minimum RF noise disturbance. The influence of quartz walls and cooling water surrounding RF plasma on the light path of this 'theta-scan' was discussed and it was found that the true lateral position chi can be deduced without knowledge of refractive indices of media. Using this method, the temperature and electron density profile in argon-hydrogen RF plasma were derived preliminarily through the Arl Boltzmann-plot and H(sub beta) Stark broadening methods. The effect of the carrier gas flow rate on the temperature profiles was also discussed. Author (NASDA)

Takeshi Usami *In its* Journal of NIRE, Vol. 2, No. 2 25 Mar. 1993 p 61-67 In JAPANESE (For primary document see N94-28675 08-25)

Avail: CASI HC A02/MF A01

The US-Japan Conference on Development and Utilization of Natural Resources (UJNR) had their first conference in Tokyo in 1964. Marine Mining Panel (MMP), one of the panels of UJNR, has had 14 meetings so far since 1970, involving in joint research activities including information and researchers exchange. The cooperation themes of MMP are: (1) Mn lumps on abyssal floors; (2) Co crust mineral deposits and underwater hydrothermal mineral deposits; and (3) sands and gravels on continental shelves. The 14th MMP meeting was held at the University of Hawaii in June 1992. After reporting and discussion on the cooperation themes, participants went on field trips to relevant organizations and facilities such as MMTC's (Marine Minerals Technology Center) and PMEL (Pacific Marine Environmental Laboratory). MMP will continue their regular meeting with the same themes once in one and half or two years. 'Natural gas and oil' may be added to the cooperation themes. Author (NASDA)

SIMILARITY SOLUTIONS AND NUMERICAL MODELING IN BUOYANCY CONTROLLED TURBULENT DIFFUSION FLAMES

David E. Ramaker 3 Feb. 1994 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-93-1-G014)

(AD-A275820) Avail: CASI HC A02

The objective of this research was to develop a fundamental understanding of the behavior of buoyancy controlled axisymmetric diffusion gas flames and liquid pool fires. Specifically, we attempted to simulate two-dimensional axisymmetric profiles of the velocity, temperature, and species and soot concentrations. Knowledge of these profiles allowed us to determine the main characteristics of the flame; i.e., the heat feed back, which in turn determines the mass burning rate of a liquid pool, the height of the flame and the power output of a fire source to the surrounding environment. QUALITATIVE VECTOR OPTIMIZATION OF A CONDENSATE STABILIZER PROCESS Plant Design Report Series
M. Hurme, J. Dohnalova, and M. Dohnal 1994 17 p
(PB94-133246; Rept-11) Avail: CASI HC A03/MF A01

A method of qualitative vector optimization is presented with an application to reasoning on a condensate stabilizer process. The method can be applied to the early stages of process design where the comparison of different alternatives is based both on quantitative and qualitative knowledge. The optimization goals are not single-criteria type but exhibit a qualitative multicriteria problem. The presented approach disintegrates one general goal into a set of subgoals which can be more objectively evaluated. NTIS

BF3 was co-condensed with H2O, D2O, (C2H5)2O, (CF3CH2)2O, and (C2F5)2O in excess argon at 15 K. Infrared spectra of BF3/water isolated in solid argon provided a more complete analysis of the BF3--H2O complex than previously published. Infrared spectra of the matrices showed a definite Lewis acid-base interaction between BF3 and diethyl ether; a weak but definite interaction with bis (2,2,2-trifluorodiethyl) ether, and no observable interaction with perfluorodiethyl ether. Thus, the ether data indicate a clear trend between strength of interaction with BF3 and the degree of F substitution. To support and explain the emerging relationship between interaction strength and the basicity of the oxygen-containing molecule, the proton affinity of (CF3CH2)2O was measured using chemical ionization mass spectrometry. The implications of the results for lubricant/metal oxide surface interactions are discussed. Author (revised)

Future Air Force aircraft fuels will contain chemical constituents that not only contribute to the propulsion of the aircraft but also to the temperature control of both the combustor walls and the aircraft body. Temperature control may require the use of new, endothermic fuels such as methylcyclohexane (MCH). This cycloalkane in the presence of a catalyst dehydrogenates to toluene. The toluene and hydrogen product, containing a small amount of unreacted MCH, fuel the combustor. The burning characteristics of the mixture as well as its temperature stability as it is transferred to the combustor, most likely as a supercritical fluid, are largely unknown. Clarifying the combustion and thermal stability characteristics of both gaseous and supercritical fluid mixtures of toluene and methylcyclohexane has been the focus of the past year's research. Gas phase flow reactor studies of the pyrolysis and oxidation of pure MCH and of the oxidation of mixtures of MCH and toluene have revealed the chemical means by which MCH affects the oxidation chemistry of toluene. Supercritical fluid flow reactor examinations of the thermolysis of MCH and toluene mixtures have suggested chemical routes to deposit formation in the fluid fuels. These results are described in greater detail in this report. DTIC

Admixture of aqueous solutions of silver nitrate and potassium chromate results in immediate precipitation of silver chromate as a red-brown microcrystalline powder, while addition of aqueous silver nitrate solution to a solution of potassium chromate/18-crown-6 in ethanol gives a bright-red precipitate. X-ray powder diffraction shows both materials to be orthorhombic silver chromate. The ethanol-derived sample displays broader diffraction peaks, suggesting smaller crystallite size. Scanning electron microscopy confirms this. The ethanol-derived sample appears amorphous, while the aqueous sample displays well-faceted crystallites approximately 0.5 - 1 micron in size. DTIC

The conference proceedings contains 38 papers that cover new technologies for low NO(x) combustors and advanced high pressure/high temperature cycle engines. The technical evaluation report and the keynote address are included at the beginning, and discussions follow most papers. The symposium was arranged in the following sessions: technology overview papers (two papers); modeling: pollutant formation (four); modeling: combustor design (five); high temperature fuels and fuel systems (six); combustion research: performance (six); combustion research: emissions (five); fuel atomization: diagnostics and modeling (five); and combustion research: flowfield and mixing (four). The last paper is a contribution from Russia not allocated to a session. For individual titles, see N94-29247 through N94-29285.

Emissions from aircraft engines include carbon dioxide, water vapor, nitrogen oxides, sulphur components, and various other gases and particles. Such emissions from high-flying global civil subsonic aircraft contribute to anthropogenic climate changes by increase of ozone and cloudiness in the upper troposphere, and by enhanced greenhouse effect. The absolute emissions by air traffic are small (a few percent of total) in comparison to

surface emissions. However, the greenhouse effect of emitted water and of nitrogen oxides at cruise altitude is large in comparison to that of the same emissions near the earth's surface because of relatively large residence times at flight altitudes, low background concentrations, low temperature, and large radiative efficiency. At present, it appears that the emissions of nitrogen oxides have changed the background concentration in the upper troposphere in between 40 deg N and 60 deg N by 100 percent, causing an increase of ozone by about 20 percent. Regionally the observed annual mean change in cloudiness is of order 0.4 percent. The resultant greenhouse effect of changes in ozone and thin cirrus cloud cover causes a climatic surface temperature change of the order 0.01 to 0.1 K. These temperature changes are small in comparison to the natural variability. Recent research indicates that the emissions at cruise altitude may increase the amount of stratospheric aerosols and polar stratospheric clouds and thereby may have an impact on the atmosphere environment, to a yet unknown degree. Air traffic is increasing by about five to six percent per year; fuel consumption grows by about three percent per year. Moreover, the climatic changes due to air traffic enhance other environmental problems originating, e.g., from anthropogenic carbon dioxide or methane emissions. Hence, air traffic induced emissions are of growing importance. This calls for the development of efficient and low-emission propulsion systems and other means to reduce the emissions. This paper surveys the state of knowledge and describes several items of results from recent and ongoing research.

The challenges in designing high performance aircraft combustion systems have not changed significantly over the years, but the approach has shifted towards a more sophisticated analytical process. Initially an overview of the U.S. Navy's component technology development procedure is presented to show how technology development is still tied into mission requirements. A more technical discussion on combustion technology status and needs will show that the classic impediments that have hampered progress towards near-stoichiometric combustion still exist. Temperature rise, mixing, liner cooling, stability, fuel effects, temperature profile control, and emissions continue to confront the aerodynamic and mechanical designers with a plethora of engineering dilemmas and trade-offs. In addition, new materials such as ceramic matrix composites (CMC) and intermetallics like titanium aluminides (TiAl) are now being incorporated into every advanced design. The process of combustion design has taken on a new meaning over the past several years as three dimensional codes and other advanced design and validation tools have finally changed the approach from a 'cut and burn' technique to a much more analytical process. All of these new aspects are now integral elements of the new equation for advanced combustion design that must be fully understood and utilized. Only then will the operable, high temperature capable combustion systems needed for future military aircraft be developed. Author

Even with it's marginal performance, Concorde has demonstrated that supersonic civil aircraft are a practical proposition. A second generation machine will need sufficiently good performance for a robust operating system that can provide reliable, frequent service with competitive economics. Additionally, the propulsion system must be acceptable environmentally. That is it must create acceptable noise levels around airports and have acceptable emissions throughout its mission including cruise. Whatever devices may be used to improve the acceptability at subsonic flight conditions, the high operating temperatures at cruise can create difficult targets for the operation of the combustion system both mechanically and in the combustion process itself. While the driving force is ever better fuel consumption and weight to achieve economic viability, a future supersonic transport engine will have cycle temperatures limited only by the mechanical integrity of the major components. The environment of the major components in modern gas turbine engines is dominated by the air delivered by the compressor system. Consequently the maximum compression temperature is governed by materials available for the turbine and compressor discs. The continued improvement of the disc material leads to combustion inlet temperatures beyond today's experience and sets difficult targets for combustion system emissions. This is worsened by the requirement being at cruise and therefore maintained for the major part of the mission. Problems such as creep and oxidation of metallic parts are also considered. The gas turbine industry is directing particular attention to very low NOx combustors, whether for aircraft or land based CCGT systems. These low NOx combustors frequently use liquid fuels or natural gas burning under very lean premixed conditions with air or under rich-lean conditions, although only the first case is studied here. In land based systems, diluted steam or nitrogen are sometimes injected into the combustion chambers to reduce flame temperature. The NOx emissions from such systems are the product of three chemical mechanisms which are interrelated: the hydrocarbon prompt NO, the thermal NO (extended Zeldovich mechanism), and the nitrous oxide route to NO. Formation of NO2 from NO also occurs, as well as emission of carbon monoxide and unburnt hydrocarbons. When the fuel-oxidant proportion decreases towards leaner conditions, flame temperatures are lowered, resulting in the total NO being reduced and the thermal-NO contribution greatly diminished to the benefit of the remaining two mechanisms of NO formation. While knowledge of the elementary reactions and their chemical kinetics concerning methane and simple hydrocarbons combustion has existed for a number of years, its use for computer modeling is limited to simple flow dynamics configurations. Nevertheless, understanding of such combusting flows under a wide range of experimental conditions allows for analogies or speculations with more complex actual systems. Such understanding can be achieved by means of one dimensional laminar premixed flame modeling, with a full chemical mechanism which incorporates the three routes of NO formation. Complementary to this understanding is the modeling of the actual combustion system using a full description of the fluid dynamics coupled with a reduced chemical scheme, which is then compared against the first model. The objective of this investigation is to evaluate the relative importance of the three mechanisms of NO formation in lean premixed methane-air combustion with increasing pressure using the one dimensional plug flow package PREMIX, and to test the validity of a three dimensional model with a global chemical mechanism against the one dimensional model in the atmospheric pressure case. Methane is chosen because it is the only mechanism which is reasonably well known and is a good guide to the behavior of other hydrocarbons. The mixture ratio chosen is richer than that in lean gas turbines, but the combustion of this mixture with the low preheat gives realistic gas turbine final flame temperatures. Conditions of NO2 formation are also analyzed in the one dimensional model and results extrapolated to the case of gas turbines. Derived from text

CFD predictions of nitric oxide and smoke production in a tubular combustor are described for a range of inlet temperature and pressure conditions up to 800 K and 8 bar, chosen to distinguish the effects of both state properties and turbulence on formation rates. Combustion models based on both laminar flamelet and chemical equilibrium representations are contrasted and compared with measurements in the literature. While uncertainties persist with respect to the detailed mechanisms, notably for soot formation, a strategy is identified which extends the role of mixture fraction in the calculation of the influence of turbulent scalar fluctuations on emissions prediction. Soot formation is an important but poorly understood subject. Although significant advances have been made in the last few years, soot formation models for numerical calculation still present recognized shortcomings. Different soot formation models are compared in the calculation of a propane turbulent diffusion flame and the influence of soot agglomeration and refractive index on soot volume fraction values inferred from extinction measurements are investigated. The time-averaged equations governing conservation of mass and momentum are closed by the k-epsilon eddy viscosity/diffusivity model and combustion is modeled using the laminar flamelet approach. Soot prediction involves the solution of transport equations for soot particle number density and soot mass fraction. The uncertainties of soot volume fractions obtained from extinction measurements due to agglomeration and the value of the complex refractive index were studied. Results using Rayleigh approximation were compared with predictions using the model presented by Iskander et al. for scattering and extinction of light by an ensemble of spherical particles. This paper focuses on the calculation of the flow and scalar fields of axisymmetric gas turbine combustion chambers with non-premixed combustion. Modelling of the turbulent swirling flow is carried out both by viscosity and Reynolds stress closure. It is our intention to specify the shortcomings as well as the potential of the different schemes with regard to prediction capabilities, numerical performance, and economic worth. The various aspects of modelling are discussed. A short description of the governing transport equations as well as the turbulence closure is given. An equilibrium chemistry model is compared to a laminar flamelet model, both schemes applied in conjunction with a probability density formulation for scalar properties. Numerical results of velocities and temperature in model gas turbine combustion chambers are compared with experimental results. Probable reasons for deviations are deduced and some prospects for possible future development of numerical simulation of gas turbine combustion are given. Author (revised)

Copyright Avail: CASI HC A03/MF A04

A method is presented for calculating steady three-dimensional two-phase turbulent reactive flows with curved irregular boundaries. The gas phase equations are solved in an Eulerian frame of reference by a numerical technique based on the finite volume approach, while the equations describing droplet motion, evaporation, and burning are treated in a Lagrangian frame of reference. Turbulent transport is described by the standard k-epsilon model. The combustion model utilizes a conserved scalar formulation and an assumed shape probability density function to account for chemistry-turbulence interaction. The numerical scheme employs structured non-orthogonal grids, a node-centered variable arrangement, and Cartesian velocity components. A special interpolation procedure is used to avoid checkerboard oscillations due to pressure-velocity coupling, and a low diffusive and bounded scheme is introduced to approximate the convective terms in the transport equations. The capabilities of the numerical procedure are demonstrated by simulating an annular combustion chamber for which experimental results were available. The agreement between calculation and experiments ranges from fair to good. Author (revised)

Multidimensional computational combustion dynamics has been used over the last twenty years to provide improved insight during gas turbine combustor design and development processes. The empirical/analytical combustor design methodology that was first demonstrated under the Army sponsored Combustor Design Criteria Validation program conducted during 1974-1978 has been used in the design and demonstration of 15 advanced rig combustors, four technology demonstrator engine combustors, three engine combustors, and one small turbine augmentor. Recognizing the limitations of turbulent combustion models, numerics, and the assumptions required to fully specify the boundary conditions for practical gas turbine combustion systems, a new technique that combines state-of-the-art turbulent combustion models with 'consistent' macro-volume expressions ('hybrid combustor modelling') was proposed. This hybrid modeling approach has been calibrated with combustors that include diffusion flame, lean premix/prevaporized, or rich-lean types of combustion processes. The hybrid modeling technique gives good 'quantitative' agreement with measured data on gaseous emissions, smoke, combustion efficiency, lean blowout fuel-air ratio, pattern factor, liner wall temperature levels, and gradients of a number of combustors. Copyright Avail: CASI HC A03/MF A04

A typical small gas turbine combustor is modelled using CFD, and the numerical results are compared with laser doppler velocimetry (LDV) measured data. The predicted flow characteristics are in excellent agreement with the measurements. Some aspects of CFD application in combustor design are discussed. CFD can be used in the following ways: as a tool in studying the flowfield development; in the optimization of location, size, and quantity of flow devices; in monitoring flow performance; and in correlating important design parameters. Use of CFD can significantly reduce the lapse time and the development cost of gas turbine combustors.

The detailed study of the aerodynamics and the thermodynamics of systems is an important part in the process of dimensioning and optimizing the afterburning chambers of modern turbojets. In this context, the article presents two examples of geometries and recent results drawn from concrete cases. The aerothermochemical code which was used was developed by ONERA within the framework of the Cooperative Action for Combustion Chambers (A3C). It is based on a volumes type technique finished with a structured three-dimensional mesh adapted to the walls. The model of combustion used of the generalized type 'Eddy Break Up' is the subject of a more detailed presentation. Author (revised)

This paper describes a study performed under contract to Air Force Wright Laboratory, Wright-Patterson Air Force Base, Dayton, OH in association with the Naval Air Propulsion Laboratory, Trenton, NJ. The study projected fuel temperature capability requirements for future tactical fighter applications and the payoffs that would be realized by achieving these capabilities. The study was approached on the basis of the maximum benefit that might be realized through the use of high temperature fuels, i.e. elimination of the recirculation system. Heat loads were projected for different missions spanning IHPTET technology phases 1, 2, and 3 at different flight conditions. Fuel temperatures across fuel system components were calculated at these heat loads. Shortfalls of the current 163 C fuel capability were shown, and minimun fuel temperature requirements were defined. The study concluded that elimination of the recirculation system is not feasible but shows how high temperature fuel capability can minimize the weight penalty associated with fuel recirculation. In this way, potential payoffs for high temperature fuel development were shown in the form of reduced weight penalties that would normally be encountered as larger and larger recirculation systems are required to accommodate the increasing heat loads projected for advanced aircraft. Increases in aircraft performance are leading to increases in the thermal stress on the primary aircraft coolant--the fuel. Fuel thermal stability limitations may offset future aircraft performance gains. The Air Force's Wright Laboratory is sponsoring several research programs to address this problem. The development of an additive package for JP-8 to improve its thermal stability is the primary focus of this paper. This program involves extensive testing of fuels and additives in a variety of test devices, culminating in tests in a fuel system simulator and engine tests. These tests involve Air Force personnel, on-site contractors (University of Dayton Research Institute, Systems Research Laboratories), Pratt and Whitney Aircraft Co., additive manufacturers, and Sandia National Laboratory. The test devices include several flowing and static tests, where the behavior of a fuel is investigated in a wide variety of environments. The study of several baseline fuels in these devices has led to some new insights into the mechanisms of fuel thermal (in)stability. It is becoming clear that a fuel's tendency to oxidize (to form peroxides, for example) is often inversely proportional to its tendency to form insoluble deposits. Author (revised)

Two global-chemistry models for oxidative deposition of jet fuels are evaluated by integrating them into a Computational Fluid Dynamics with Chemistry (CFDC) code. A previously developed two-step global-chemistry model was found to be insufficient to describe the thermal-oxidation and -deposition rates associated with a Jet-A fuel. A new global-chemistry model has been developed systematically based on observations from flowing and static experiments. The global-autoxidation reaction is modified such that the reaction rate becomes zeroth-order with respect to the dissolved oxygen concentration. The generation of deposit-forming precursor is coupled with the autoxidation reaction by introducing a radical species ROO. A formulation for the sticking probability has also been developed. Deposition profiles are well represented by this new model under a variety of temperature and flow conditions. The model correctly predicts the changes in magnitude and spatial location of the deposition peak due to changes in flow. The CFDC model, which is designed for flowing systems, has been extended to static experiments. The model incorporates a non-depleting species F(sub s) representing all non-oxygen compounds responsible for deposition. Static experiments were found to provide a useful and inexpensive method for estimating the concentration of F(sub s) in the fuel. Author

FUEL INJECTOR DESIGN FOR HIGH TEMPERATURE AIRCRAFT ENGINE **c07**

R. W. Stickles, W. J. Dodds, T. R. Koblish, J. Sager, and S. Clouser *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 12 p (For primary document see N94-29246 08-25)

(Contract N00140-87-C-6321)

Copyright Avail: CASI HC A03/MF A04

The objective of the Innovative High Temperature Aircraft Engine Fuel Nozzle Program was to design and evaluate a nozzle capable of operating at a combustor inlet air temperature of 1600 F (1144 K) and a fuel temperature of 350 F (450 K). The nozzle was designed to meet the same performance requirements and fit within the size envelope of a current production dual orifice fuel nozzle. The design approach was to use improved thermal protection and fuel passage geometry in combination with fuel passage surface treatment to minimize coking at these extreme fuel and air temperatures. Heat transfer models of several fuel injector concepts were used to optimize the thermal protection, while sample tube coking tests were run to evaluate the effect of surface finish, coatings and tube material on the coking rate. Based on heat transfer analysis, additional air gaps, reduced fuel passage flow area and use of ceramic tip components reduced local fuel wetted wall temperatures by more than 200 F (100 K) when compared to a current production fuel nozzle. Sample tube coking test results showed the importance of surface finish on the fuel coking

rate. Therefore, a one micro-inch (0.025 micron) roughness was specified for all fuel passage surfaces. A novel flow divider valve in the tip was also employed to reduce weight, allow room for additional thermal protection, and provide back pressure to reduce the risk of fuel vaporization. The fuel nozzle was fabricated and evaluated in a series of high temperature coking tests. Initial results of these tests indicate that thermal protection and surface treatments were partially successful in preventing nozzle fouling, but additional refinement of the internal flowpath is needed to prevent buildup of coke particles that partially blocked the spin slots which meter the nozzle fuel flow. The causes of fuel injector spray deterioration and the effects of this deterioration on engine durability and performance are discussed. Small aircraft gas turbine fuel injectors present special design challenges due to low fuel flow rates involved and the physical size limitations. The principal fuel injector performance requirements are discussed in relation to their effect on the hydraulic, aerodynamic, and thermal design of aerating fuel injectors. Author

THE EFFECT OF INCOMPLETE FUEL-AIR MIXING ON THE LEAN LIMIT AND EMISSIONS CHARACTERISTICS OF A LEAN PREVAPORIZED PREMIXED (LPP) COMBUSTOR

D. A. Santavicca, R. L. Steinberger, K. A. Gibbons, J. V. Citeno, and S. Mills *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 12 p Sponsored by NASA. Lewis Research Center and GE (For primary document see N94-29246 08-25)

Results are presented from an experimental study of the effect of incomplete fuel-air mixing on the lean limit and emissions characteristics of a lean, prevaporized, premixed (LPP), coaxial mixing tube combustor. Two-dimensional exciplex fluorescence was used to characterize the degree of fuel vaporization and mixing at the combustor inlet under non-combusting conditions. These tests were conducted at a pressure of 4 atm., a temperature of 400 C, a mixer tube velocity of 100 m/sec and an equivalence ratio of .8, using a mixture of tetradecane, 1 methyl naphthalene and TMPD as a fuel simulant. Fuel-air mixtures with two distinct spatial distributions were studied. The exciplex measurements showed that there was a significant amount of unvaporized fuel at the combustor entrance in both cases. One case, however, exhibited a very non-uniform distribution of fuel liquid and vapor at the combustor entrance, i.e., with most of the fuel in the upper half of the combustor tube, while in the other case, both the fuel liquid and vapor were much more uniformly distributed across the width of the combustor entrance. The lean limit and emissions measurements were all made at a pressure of 4 atm. and a mixer tube velocity of 100 m/sec, using Jet A fuel and both fuel-air mixture distributions. Contrary to what was expected, the better mixed case was found to have a substantially leaner operating limit. The two mixture distributions also unexpectedly resulted in comparable NO(x) emissions, for a given equivalence ratio and inlet temperature, however, lower NO(x) emissions were possible in the better mixed case due to its leaner operating limit. A prime requirement in the design of a modern gas turbine combustor is good lean blowout (LBO) stability to ensure an adequate stability margin. Therefore, a geometrically simple, optically accessible, and acoustically decoupled research combustor was designed to reproduce the gross features of the flow field in a modern annular gas turbine combustor. Its LBO was measured using methane and propane fuels. We successfully observed and documented a systematic and detailed sequence of events comprising an attached flame, a lifted shear flame, an intermittent shear flame, the large-scale instability of the flame front, and LBO. Also, for the sake of comparison, a generic gas turbine combustor was tested and its LBO limits were measured. We found that LBO in the research combustor behaved like a perfectly stirred reactor (PSR) for values of combustor-loading spanning three orders of magnitude. Also, LBO was successfully correlated using a simple PSR theory. Finally, Swithenbank's dissipation gradient approach and an eddy dissipation model with a built-in characteristic extinction time criterion, when coupled with CFD, offer the possibility of an a priori calculation of LBO. The lean stability of a generic gas turbine combustor at peak heat release rates was less than that in a research combustor. Also, in the generic combustor, the flame changes from a lifted to an attached position depending upon how combustor loading is achieved. Due to such complications, modeling of the LBO process that works reasonably well with the research combustor will be seriously challenged by the blowout behavior evidenced in the generic gas turbine combustor. Three low NOx gas turbine combustor design concepts, Jet Mix, Grid Mix and radial swirlers, which have been demonstrated to give very low NOx emissions using gaseous fuels have been successfully tested on liquid fuels and low NOx emissions demonstrated. The Jet Mix was shown to have low NOx emissions at atmospheric pressure and has been tested at pressure, with similar low NOx results. Kerosene performance and emissions was very similar to that for propane as the fuel. The scale up of the Jet Mix was found to be possible without increasing the NOx emissions greatly and is a preferable design option to the use of large numbers of smaller Jet Mix modules. Sector tests at pressure showed the Jet Mix design produced emission reductions close to the best of the NASA clean combustor results. The Grid Mix low NOx design was shown to be capable of low NOx performance using kerosene. There was a much wider flame stability than for the Jet Mix design and lower NOx emissions were demonstrated. The radial swirler with vane passage of 76mm wall fuel injection was shown to have ultra low NOx emissions with liquid fuels, only slightly higher than for gaseous fuels. For a high air flow radial swirler it was found that central kerosene injection gave lower NOx emissions than for gaseous fuels and had the potential to yield a NOx EI of below 10 at simulated take off conditions. The first results of a research and development program on combustion characteristics of gaseous hydrogen fuel in a 'can' type gas turbine combustor, both in combination with air or with oxygen and water, are here presented. Application of a H2/O2/H2O combustion chamber is suggested for the launch-boost phase of an advanced turboramjet. Experiments have been conducted to determine the configuration and the operation of the hydrogen-air combustion chamber test facility, to be transferred to two different kinds of small power turboshafts. Computations, project details and tests, are presented regarding high pressure and temperature stoichiometric H2/O2 combustion in which water is gradually injected. Referring to an already realized and operated (on behalf of the author) H2/O2/H2O combustor for a water steam closed cycle in a turbine/alternator electrically propelled automobile, a detailed design is

developed for a quite higher steam temperature, as required in high performance boost phase of a low noxious emission advanced turboramjet, in which H2 and O2 are stored in liquid form. Author

A unique test capability has been defined and used at the United Technologies Research Center to evaluate the transient response of advanced gas turbine combustors. This UTC Transient Combustion Facility offers the opportunity to achieve pre-defined time variations of the air and fuel flow rates and air temperature delivered to a combustor model. This capability can be used for model scales ranging from multi-nozzle combustor sectors to smaller setups focusing on one component or process. A dedicated control computer aids in establishing time profiles for the input parameters and automatically executing the transient test. Among its applications, the facility has been used to study the occurrence of in-nozzle fuel vaporization during Bodie cycles and to assess the tolerance of a fuel-staged combustor to rapid fuel redistribution. To develop a component of an advanced aircraft engine, heavy experimental activities are necessary. To avoid very long and expensive test campaigns on development engines, tests on the so-called technology rigs are fundamental. Particularly in the case of combustion components, whose analytical simulations by means of computer code are still not completely satisfactory and where very high gas temperatures may cause important problems of mechanical integrity, it is essential to check the behavior of the component on the rig before testing on the engine. This paper gives an overview of the test rigs which are used by FiatAvio in the development of the afterburner system for an advanced fighter aircraft engine. The tests which are carried out on these rigs are described and some of the most important results are reported, discussing the benefit they have given to the engine development. Even if this paper obviously does not cover all the results obtained from rig tests over years of engine development, the few examples reported clearly show the importance of these rigs and confirm that the financial outlay to build and update the rigs, test plants and models is worthwhile. Conventional and advanced gas turbine engines are coming under increased scrutiny regarding pollutant emissions. This, in turn, has created a need to obtain in-situ experimental data at practical conditions, as well as exhaust data, and to obtain the data in combustors that reflect modern designs. The in-situ data are needed to (1) assess the effects of design modifications on pollutant formation, and (2) develop a detailed data base on combustor performance for the development and verification of computer modeling. This paper reports on a novel high pressure, high temperature facility designed to acquire such data under controlled conditions and with access (optical and extractive) for in-situ measurements. To evaluate the utility of the facility, a model gas turbine combustor was selected which features practical hardware design, two rows of jets (primary and dilution) with four jets in each row, and advanced wall cooling techniques with laser drilled effusive holes. The dome is equipped with a flat-vaned swirler with vane angles of 60 degrees. Data are obtained at combustor pressures ranging from 2 to 10 atmospheres of pressure, levels of air preheat to 427 C, combustor reference velocities from 10.0 to 20.0 m/s, and an overall equivalence ratio of 0.3. Exit plane and in-situ measurements are presented for HC, O2, CO2, CO, and NO(x). The exit plane emissions of NO(x) correspond to levels reported from practical combustors and the in-situ data demonstrate the utility and potential for detailed flow field measurements. Author

As part of an ongoing program of continuous improvement by control of gaseous emissions from the combustors of gas turbines, a unique fuel-staged annular combustor is being developed for application to current and future Pratt & Whitney aircraft engines. The configuration advantages of this combustor are outlined, and discussions are presented on staging considerations and fuel system impacts. Development of the fuel-staged combustor is described by reference to supporting mixing experiments and computational fluid dynamic studies, and rig tests at high pressures. Measured results are given appropriate for the International Aero Engines (IAE) V2500 engine that show progressive reductions in achieved emissions compared to the goals established for this program. The pollutants emissions decrease doesn't seem easily achievable, particularly with advanced engines cycles conditions with high pressure, temperature, and fuel to air ratio. For a given fuel and air split, the combustor size can't be reduced without leading to relight altitude, combustion stability, and emissions concerns. In addition, the liners areas to be cooled remain considerable, the cooling airflow increase leads to higher fuel to air ratio in the primary zone and finally to unacceptable Nox emissions levels due to higher flame temperatures. In order to satisfy the trade off in between the combustor performance at low and high engine ratings, several combustor concepts are in development. Among them, the use of variable geometries to modulate the primary zone airflow seems promotive. Indeed, this concept allows to satisfy the compromise between the different ratings taking into account the decrease of the combustor panels areas to be cooled. That is the reason why this variable geometry concept is particularly suitable to high pressure and temperature engines cycles. In this paper, test results recorded on a five-cups sector fitted with a variable geometry injection system, and some measured performance on a full annular combustor are commented. It appeared that acceptable performance in term of combustion stability can be met with a low volume combustor. The cooling airflow reduction and the primary zone fuel to air ratio control allow to meet quite good and homogeneous combustor exit temperature profiles whatever the engine rating. Author

This paper summarizes the work undertaken by the Defense Research Agency (DRA Pyestock) for the BRITE/EURAM Low Emissions Combustor Technology Project No 1019. The work was jointly funded by the CEC (DGXIIH), the UK DTI (CARAD - ATF4) and the UK MOD (DCSA). The gas turbine emissions problem is summarized and the design philosophy of the experimental program is described. The principal objective was to demonstrate a simultaneous reduction of NO(x) and smoke emissions together with acceptable idling emissions and stability in an unstaged combustor. A secondary objective was to demonstrate the extent to which NO(x) and smoke could be reduced if the combustor was to be used as the main stage of a staged combustor where a poorer idling performance could be accepted. The work consisted of a parametric investigation of the principal factors controlling the emissions produced in the combustor primary zone. Particular emphasis was placed on the influence of the distribution, number, and size of air entry holes and of residence time on pollutant formation. The results from the complete experimental program are summarized. These suggest that NO(x) reductions of about 30-40 percent should be possible together with excellent smoke and idling performance. The results suggest that NO(x) was formed very close to stoichiometric flame temperatures even at very weak combustor mixture strengths and under well mixed conditions. The reductions that were achieved were largely as a result of reductions of residence time. Author

EFFECTS OF HYDROGEN ADDITION ON POLLUTANT EMISSIONS IN A GAS TURBINE COMBUSTOR
J. Salva and G. Lopez *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 9 p (For primary document see N94-29246 08-25)
Copyright Avail: CASI HC A02/MF A04

This paper presents an experimental work on the control of pollutants produced in a tubular hydrocarbon fueled combustor, by the injection of hydrogen in small quantities (less than 4 percent of total fuel). Hydrogen is introduced in the primary zone premixed with the air. Using this technique, with lean primary zone, it is possible to reduce the NO(x) emission level while maintaining CO and HC emission index at normal levels (CO and HC levels are greater without hydrogen injection). Injecting butane, instead of hydrogen, shows that there is no beneficial effect, so the influence of hydrogen in CO and HC reduction is due mainly to factors such as hydrocarbon substitution and chemical kinetics. An analysis to estimate the contribution of these factors is also included. Author

Reaction progress in premixed methane-air flames in round ducts without and with kerosene sprays has been quantified on the basis of species concentration measurements for different fueling arrangements of kerosene with equivalence ratio, proportion of liquid to gaseous fuel, duct length and air preheat temperature as variables in smooth and in rough combustion. The intensity of heat release close to the flame holder in rough combustion was greater than that in smooth combustion, and the duct length necessary to ensure complete combustion decreased with air preheat temperature and upstream turbulence intensity and was weakly dependent on the proportion of methane to kerosene in flow arrangements where the kerosene was sprayed upstream of the flame-holder. The injection of kerosene through the flame holder at a velocity larger than that of the mean flow past the disk led to uneven mixing and incomplete combustion. Pulsed injection of kerosene through a pintle-type injector also resulted in incomplete combustion due to the larger droplet size than in arrangements with a steady flow of kerosene. Oscillations of large amplitude were induced at equivalence ratios usually associated with smooth combustion and oscillations in rough combustion ameliorated by pulsed injection of kerosene comprising around 10 percent of the total fuel. The next generation of commercial aircraft will include turbofan engines with performance levels significantly better than those in the current fleet. Control of particulate and gaseous emissions will also be an integral part of the engine design criteria. These performance and emission requirements present a technical challenge for the combustor: control of the fuel and air mixing and control of the local stoichiometry will have to be maintained much more rigorously than with combustors in current production. A better understanding of the flow physics of liquid fuel spray combustion is necessary. This paper describes recent experiments on spray combustion where detailed measurements of the spray characteristics were made, including local drop-size distributions and velocities. Also, an advanced combustor CFD code has been under development and predictions from this code are compared with experimental results. Studies such as these will provide information to the advanced combustor designer on fuel spray quality and mixing effectiveness. Validation of new fast, robust, and efficient CFD codes will also enable the combustor designer to use than as valuable additional design tools for optimization of combustor concepts for the next generation of aircraft engines. Copyright Avail: CASI HC A03/MF A04

This paper presents experimental results, numerical models, and simulations relating to the behavior of the liquid phase in combustion chambers. These studies concern the initial conditions, boundary conditions, and validations of the models of the various physical processes which must be integrated into the computer codes of reactive flows. Several experiments are presented: characterization of a jet of drops at the aerodynamic exit of a burner, dispersion of the drops in a screen turbulence and a strongly nonstationary flow, trajectories and evaporation of the drops in a turbulent flow, and interaction of the drops with a hot wall. The characterizations of the diphasic flows are carried out by LDA and hot wire for the gas phase and by phase Doppler anemogranulometry and rapid video techniques associated with image processing for the liquid phase. Video techniques and image processing make it possible to restore the trajectories of the drops, their speed as well as the main statistics of dispersion (average trajectory, envelope, and presence rate). The experimental results, in particular those coming from the dispersion of the drops, are compared with the numerical results of simulations. The Lagrangian method is used for transport of the drops, and their dispersion can be calculated starting from the following two approaches: the gas phase is calculated by direct simulation and a deterministic model is retained for the transport of the drops; and the gas phase is calculated starting from a model of turbulence of the type K- and stochastic models are used for the transport of drops. In conclusion, the models most appropriate to the diphasic flows studied are deduced. Author (revised)

A NEW EULERIAN MODEL FOR TURBULENT EVAPORATING SPRAYS IN RECIRCULATING FLOWS
S. Wittig, M. Hallmann, M. Scheurlen, and R. Schmehl *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep.

1993 11 p Sponsored by Arbeitsgemeinschaft Hochtemperatur Gasturbine and DFG (For primary document see N94-29246 08-25)
Copyright Avail: CASI HC A03/MF A04

A new Eulerian model for the computation of turbulent evaporating sprays in recirculating flows is derived. It comprises droplet heating and evaporation processes by solving separate transport equations for the droplet's temperature and diameter. Full coupling of the droplet and the gaseous phase is achieved by the exchange of source terms due to momentum, heat, and mass transfer. The partial differential equations describing the droplet's transport and evaporation in the new method can be solved using the same numerical procedure as for the gas phase equations. The validity of the model is established by comparison with a well known Lagrangian approach and with experimental data. For this purpose calculations of a recirculating droplet charged air flow within a model combustor are presented. Author (revised)

An experimental investigation was conducted to examine the operating and spray characteristics of two internal-mixing twin-fluid atomizers that were designed to produce effervescent atomization at low air/liquid mass ratios (ALR's). These two experimental atomizers ejected the two phase flow so as to produce a wide spray angle. One atomizer was a plain orifice design that used a four-hole exit orifice which divided and turned the two phase flow just prior to ejection. The other atomizer, called the conical sheet atomizer, ejected the two phase flow through an annular passage in such a way as to form a hollow cone spray. The atomizer operating parameters varied during this investigation were the air/liquid mass ratio, atomizer operating pressure, and, in the case of the conical sheet atomizer, the exit gap width. Studies of spray characteristics included measurements of the spray Sauter mean diameter (SMD), drop size distribution, and, for the conical sheet atomizer, circumferential distribution of the liquid mass within the spray. For both atomizers it was found that SMD decreases with an increase in either ALR or operating pressure. The effect of ALR on SMD diminishes as the value of ALR increases. For the conical sheet atomizer, when operating at low values of pressure and ALR, SMD increases with increase in gap width, but the influence of gap width on SMD diminishes with an increase in either pressure or ALR. At the highest operating pressure of the conical sheet atomizer (552 kPa), SMD is independent of gap width at all ALR's. For both atomizers, changes in operating pressure and ALR have little effect on the distribution of drop sizes in the spray. Author (revised)

THE MIXING PROCESS IN THE QUENCHING ZONE OF THE RICH-LEAN-COMBUSTION CONCEPT
Th. Doerr and D. K. Hennecke *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 9 p Sponsored by DFG Original contains color illustrations (For primary document see N94-29246 08-25)
Copyright Avail: CASI HC A02/MF A04

The rich burn/quick quench/lean burn (RQL) combustion system is a potential concept to reduce both NO(x) and CO, UHC emissions. In view of the concept's crucial mixing process, an experimental investigation of a nonreacting multiple jet mixing with a confined crossflow has been conducted. Temperature distributions, mixing rate, and standard deviation were determined for measurements with round jet orifices by parametric variation of flow and geometric conditions. The results show that best mixing strongly depends on an optimum momentum flux ratio. Too high ratios yield a deterioration of mixing process, due to the mutual impact of opposed entraining jets. Furthermore, over a wide range of geometries investigated, inline and staggered configurations provide similar mixing rates. An appreciable enhancement of mixing with staggered orifice configurations only occurs for high momentum flux ratios and large spacings. Author

INVESTIGATION OF THE TWO-PHASE FLOW IN A RESEARCH COMBUSTOR UNDER REACTING AND NON-REACTING CONDITIONS **c34**
C. Hassa, A. Deick, and H. Eickhoff *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 12 p Sponsored by TECFLAM (For primary document see N94-29246 08-25)
Copyright Avail: CASI HC A03/MF A04

The flow resulting from an airblast atomizer with prefilmer and corotating swirl was investigated in a cylindrical combustion chamber. Gas and droplet velocities were measured by a phase Doppler anemometer and species and gas temperature by gas sampling probes respectively, thermoelements at atmospheric conditions and without fuel and air preheat. Because of interference with the liquid phase, the species measurements were restricted to a minimum distance of 40 mm from the atomizer lip. The temperature measurements showed the dominating influence of the external recirculation zone on flame stabilization for the investigated nozzle configuration with a small expansion angle of the swirling flow. The species concentration fields exhibit homogeneous radial profiles at an axial distance of 100 mm behind the atomizer, although droplets are observed up to 140 mm. Integrating the measured liquid volume flux density profiles, it was found that the fuel flux at 45 mm behind the atomizer had diminished to 14 percent of the maximum measured value. The axial profile of the liquid flux weighted Sauter mean diameter is almost linearly increasing from 22 to 31 micrometers. Systematic experimental errors and losses of the system sensitivity, which enter the results partly with opposite signs, have an influence on the measured flux densities and moments of the particle size distribution. The measurement of individual flux density profiles was reproducible to within 45 percent. A comparison between the gas flow in the nearfield of the atomizer under reacting and nonreacting conditions showed a partial suppression of the expansion of the velocity profiles by the hot corner vortex. Together with the combustion induced axial acceleration, the thus effected reduction of the effective swirl number leads to the breakdown of the recirculation at 29 mm. Author (revised)

TIME-RESOLVED MEASUREMENTS IN A THREE DIMENSIONAL MODEL COMBUSTOR **c34**
R. Jeckel and S. Wittig *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 15 p Sponsored by Arbeitsgemeinschaft Hochtemperatur Gasturbine and BMFT (For primary document see N94-29246 08-25)
Copyright Avail: CASI HC A03/MF A04

Locally and time-resolved measurements of the velocity, temperature, and species concentration in a three dimensional jet-stabilized combustor are presented. The combustor was developed at the Institute for Thermal Turbomachinery, University of Karlsruhe, for extended benchmark experiments. For the present investigation, the combustor was fired by propane. The profiles of the velocity, temperature, and species distribution were determined at seven planes along the combustor axis. A comparison between the cold flow and the reacting hot gas conditions is given. The time-resolved velocity and temperature measurements were performed by a two component LDA-system as well as specially designed and optimized thermocouple probes. The time-dependent analysis demonstrates that the velocity and turbulence and/or the temperature fluctuations are dramatically increased under hot combusting conditions. Finally, the locally determined species distributions are compared with the global concentrations at the exit of the combustor providing a data base for numerical tests.

TEMPERATURE AND COMBUSTION ANALYSIS OF COMBUSTOR WITH ACOUSTICALLY CONTROLLED PRIMARY ZONE AIR-JET MIXING
P. J. Vermeulen, V. Ramesh, B. Sanders, and J. Odgers *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 13 p (For primary document see N94-29246 08-25)
(Grant NSERC-A-7801)
Copyright Avail: CASI HC A03/MF A04

A small tubular combustor of normal design and behavior, employing acoustically controlled primary zone air-jet mixing processes, has been

successfully tested at scaled 1/4 load operating conditions, and some data was obtained at 1/2, 3/8, and 3/4 loads. The acoustic control produced a distinct richening effect, measured just downstream of the primary zone, which produced a decrease in combustion efficiency and a somewhat increased and flatter combustion gas temperature distribution. The prime cause of richening was due to combustor flow blockage caused by acoustically enhanced jet penetration. This, and the secondary effect of acoustically shed jet toroidal vortices, resulted in up to 35 percent increase in mixing, relative to 'no-drive' measured just downstream of the primary zone. The acoustic drive produced a more uniform exit plane temperature pattern, resulting in up to 35 percent improvement in mixing relative to 'no-drive' and in up to 20 percent relative improvement in the temperature pattern quality. The effects depend on air/fuel ratio and, in general, improved relative to 'no-drive' with richening. At 3/4 load, 150 W single driver power, the acoustic driving effectiveness was reduced by about 80 percent with correspondingly reduced improvements in mixing and quality. The effects of acoustic drive were favorably controllable by means of the driving power, and the exit plane data showed increased flow blockage caused by increased jet penetration by the acoustic drive was the major control mechanism.

ENDOTHERMIC FUELS FOR HYPERSONIC AVIATION c28

Leonid S. Ianovski and Clifford Moses *In* AGARD, Fuels and Combustion Technology for Advanced Aircraft Engines Sep. 1993 8 p (For primary document see N94-29246 08-25)

Copyright Avail: CASI HC A02/MF A04

The creation of hypersonic vehicles and the use of jet engines with higher temperature cycles has resulted in a significant increase in the thermal stresses of the engine elements. In order to use the fuel as the coolant for these elements, it is necessary to increase the heat capacity of hydrocarbon fuels. This problem can be solved by taking advantage of such high temperature chemical processes as catalytic dehydrogenation and thermal cracking or pyrolysis of hydrocarbon fuels, including the addition of the initiators and catalysts. The chemical heat capacity of hydrocarbon fuels can be used for the direct cooling of such elements as combustion chambers, nozzles, and front wing edges; indirect cooling of these elements can be accomplished by using a heat-transport medium in the fuel/air or fuel/gas heat exchangers. The gaseous products of the decomposed fuels can be used as a working medium for the drive of the equipment of a fuel/feeding system.

TEMPLATE SYNTHESIZED NANOSCOPIC GOLD PARTICLES: OPTICAL SPECTRA AND THE EFFECTS OF PARTICLE SIZE AND SHAPE

Colby A. Foss, Jr., Gabor L. Hornyak, Jon A. Stockert, and Charles R. Martin 25 Jan. 1994 43 p

(Contract N00014-82-K-0612)

(AD-A275378; TR-91) Avail: CASI HC A03/MF A01

We have prepared nanoscopic gold cylinders of controlled radius and aspect ratio via electrodeposition of the metal within the pores of anodically-grown porous aluminum oxide membranes. The nanocylinder radii are determined by the pore dimensions of the host alumina which, in turn, depend on anodization conditions. The particle aspect ratios were controlled by varying the amount of Au deposited within the pores. The optical spectra of the gold nanocylinder/alumina composites exhibit strong absorption bands in the visible spectrum. The extinction maxima (Lambda max) values for gold particles approaching sphere-like geometry agree well with Mie Theory calculations. The blue shift of Lambda max as the particle aspect ratio is increased in qualitative agreement with Maxwell-Garnett Theory. We propose a simple modification of Maxwell-Garnett Theory that addresses both size and shape effects.

FUEL-RICH CATALYTIC COMBUSTION OF A HIGH DENSITY FUEL

Theodore A. Brabbs (Sverdrup Technology, Inc., Brook Park, OH.) and Sylvia A. Merritt Washington Jul. 1993 13 p

(RTOP 505-62-52)

(NASA-TP-3281; E-7298; NAS 1.60:3281) Avail: CASI HC A03/MF A01

Fuel-rich catalytic combustion (ER is greater than 4) of the high density fuel exo-tetrahydrocyclopentadiene (JP-10) was studied over the equivalence ratio range 5.0 to 7.6, which yielded combustion temperatures of 1220 to 1120 K. The process produced soot-free gaseous products similar to those obtained with iso-octane and jet-A in previous studies. The measured combustion temperature agreed well with that calculated assuming soot was not a combustion product. The process raised the effective hydrogen/carbon (H/C) ratio from 1.6 to over 2.0, thus significantly improving the combustion properties of the fuel. At an equivalence ratio near 5.0, about 80 percent of the initial fuel carbon was in light gaseous products and about 20 percent in larger condensable molecules. Fuel-rich catalytic combustion has now been studied for three fuels with H/C ratios of 2.25 (iso-octane), 1.92 (jet-A), and 1.6 (JP-10). A comparison of the product distribution of these fuels shows that, in general, the measured concentrations of the combustion products were monotonic functions of the H/C ratio with the exception of hydrogen and ethylene. In these cases, data for JP-10 fell between iso-octane and jet-A rather than beyond jet-A. It is suggested that the ring cross-linking structure of JP-10 may be responsible for this behavior. All the fuels studied showed that the largest amounts of small hydrocarbon molecules and the smallest amounts of large condensable molecules occurred at the lower equivalence ratios. This corresponds to the highest combustion temperatures used in these studies. Although higher temperatures may improve this mix, the temperature is limited. First, the life of the present catalyst would be greatly shortened when operated at temperatures of 1300 K or greater. Second, fuel-rich catalytic combustion does not produce soot because the combustion temperatures used in the experiments were well below the threshold temperature (1350 K) for the formation of soot. Increasing the temperature above this value would remove the soot-free nature of the process. Since all the fuels studied show a similar breakdown of the primary fuel into smaller molecular combustion products, this technique can be applied to all hydrocarbon fuels.

LIQUID-OXYGEN DROPLET VAPORIZATION AND COMBUSTION: ANALYSIS OF TRANSCRITICAL BEHAVIOR AND APPLICATION TO LIQUID-ROCKET COMBUSTION INSTABILITY Ph.D. Thesis

Jean-Pierre Delplanque 1993 223 p

Avail: Univ. Microfilms Order No. DA9315775

The behavior of a liquid-oxygen (LOX) droplet vaporizing and burning in gaseous hydrogen at conditions supercritical for both propellants is investigated using modelling/numerical techniques. First, high-pressure phase-equilibrium computations are implemented for the oxygen/hydrogen system using the Redlich-Kwong equation of state. The chosen approach is then to consider the idealized case of an isolated LOX droplet in a quiescent environment and successively include consequential features such as convection, combustion, and the effect of neighboring droplets in an array. Results show that in a quiescent environment the surface temperature reaches the critical mixture value and the droplet lifetime is subsequently controlled by the regression of the critical interface. The details of the diffusion layer of dissolved hydrogen do not affect the results significantly. However, when convection is included, it is shown that, at the conditions prevalent in a rocket engine, the reduced surface tension causes a LOX droplet to undergo boundary layer stripping for most of its lifetime. Evaluation of the stripping rate shows that it is much larger than the vaporization rate and reduces the predicted droplet lifetime by at least one order of magnitude. The film model is modified to include the effect of stripping on the heat transfer into the droplet. In most cases, stripping precludes criticality at the interface. Application of this new model to the prediction of flame spread in an idealized LOX droplet array configuration shows that high

temperatures in the reaction zone cause the droplet surface temperature to reach the critical mixing conditions even when stripping is included. However, the droplet lifetime is still controlled by the stripping rate. The model is then applied to oscillatory LOX droplet vaporization (isolated) and combustion (array). The predicted response factor spectra are compared to the results yielded by the (n - tau) model and show that the gasification process can drive the instability if it is rate-controlling. Stripping is shown to affect significantly the range of frequencies in which the gasification process is driving combustion instabilities. In view of liquid-rocket combustion instability applications, the response of a droplet in an array is compared to the response of an isolated droplet. Dissert. Abstr.

LIFTED TURBULENT JET FLAMES Ph.D. Thesis
Jay Alan Hammer 1993 155 p
Avail: Univ. Microfilms Order No. DA9325355

Experiments were conducted on lifted, turbulent jet diffusion flames. An automated technique was implemented to measure the temporal history of the liftoff height h. For the fuels investigated, the mean liftoff height h-bar has a linear dependence on exit velocity U(sub s), with a slight dependence on Reynolds number. A strain-rate model for liftoff, based on far-field scaling of turbulent jets, provides an explanation for the linear dependence of h-bar on U(sub s). When air is premixed with the fuel, the slope of the h-bar versus U(sub s) line increases faster than predicted by far-field scaling of turbulent jets. The amplitudes of the fluctuations of h are of the order of the local large scale of the jet. As h-bar increases, there is a slight increase in normalized fluctuation level h'/h-bar. The time scales of the fluctuations of h are considerably longer than the local large-scale time of the turbulence tau(sub delta). By using fuels of different chemical times to vary tau(sub delta), the measured correlation time tau(sub 1/2) normalized by tau(sub delta) was found to collapse with Richardson number xi(sub h). Experiments in which the nozzles were oriented horizontally showed no change in tau(sub 1/2), however. To investigate alternative explanations for the collapse of tau(sub 1/2)/tau(sub delta) with xi(sub h), the flame length L was measured simultaneously with h. L(t) is nearly uncorrelated with h(t), dismissing the possibility that a feedback mechanism from L to h controls the fluctuations of h. Simultaneous measurements of h and the visible radiation I were also made. For the most sooting fuel, acetylene, I(t) is highly correlated with h(t). This correlation is not the cause of the large values of tau(sub 1/2)/tau(sub delta) for that fuel, however. Non-sooting hydrogen/ethane flames were found to have values of tau(sub 1/2)/tau(sub delta) comparable to those of acetylene. Another experiment was conducted in which two dimensional images of fuel concentration (CH4) and reaction zones (indicated by CH) were obtained. The images showed a wide variety of structure types. The flame stabilization position showed large fluctuations in both the axial and radial directions. The shot to shot variation in methane number density at the flame base was also large. Dissert. Abstr.

NON-INVASIVE TEMPERATURE MEASUREMENTS USING ELECTRON PARAMAGNETIC RESONANCE SPECTROSCOPY Ph.D. Thesis
Joseph John Eckburg 1993 120 p
Avail: Univ. Microfilms Order No. DA9314862

A system has been developed that may be used for noninvasive in vivo temperature measurements in living systems. We use the nitroxide, 3-doxyl-5 alpha-cholestane, mixed in 1 mol percent cholesterol and 99 mol percent methyl docosanoate and encapsulated in proteinaceous microspheres (average diameter less than 2 micron). We have shown a dramatic and measurable change in the EPR spectral line shape between 38 and 48 C. This technique has many potential clinical applications, especially in optimizing the treatment of cancer with hyperthermia. Using the mid-field to high-field peak height ratio of the EPR spectra as the temperature dependent parameter, the temperature resolution for this system is 0.2 C. Encapsulation of the mixture in the microspheres provides two critical functions. First, the microspheres are easily injectable since they are smaller than the diameter of capillaries and are suspended in water. Second, the microspheres separate the mixture from the surrounding environment, thereby protecting the nitroxide from bioreduction and ensuring that the shape of the EPR spectrum is greatly affected by temperature in the range of the medium's liquid-solid transition. There was a hysteresis effect seen in the spectral line shape for this system as the temperature was raised and then lowered between 37 and 48 C. However, if the temperature of the system is kept above or below a certain critical temperature and within a small temperature range (less than 3 C), the hysteresis can be avoided and accurate temperature measurements can be made. In order to increase the temperature resolution, computer simulation of the EPR spectra for the temperature measurement system was attempted. The no motion limit and fast motion limit spectra for the system were successfully simulated. Initial attempts to simulate the spectra for the system between 38 and 48 C were unsuccessful. Dissert. Abstr.

ELECTROCHEMICAL INCINERATION OF WASTES Final Report
J. O. M. Bockris, R. C. Bhardwaj, and C. L. K. Tennakoon Jan. 1993 49 p
(Grant NAGw-1779)
(NASA-CR-195262; NAS 1.26:195262) Avail: CASI HC A03/MF A01

There is an increasing concern regarding the disposal of human wastes in space vehicles. It is of utmost importance to convert such wastes into harmless products which can be recycled into an Environmental Life Support System (CELSS), which incorporates the growth of plants (e.g. wheat) and algae to supplement the diet of the astronauts. Chemical treatments have proven relatively unsatisfactory and tend to be increasingly so with increase of the mission duration. Similarly, the use of heat to destroy wastes and convert them to CO2 by the use of air or oxygen has the disadvantage and difficulty of dissipating heat in a space environment and to the inevitable presence of oxides of nitrogen and carbon monoxide in the effluent gases. In particular, electrochemical techniques offer several advantages including low temperatures which may be used and the absence of any NO and CO in the evolved gases. Successful research has been carried out in the electrochemical oxidation of wastes over the last several years. The major task for 1992 was to conduct parametric studies in preparation for the building of a breadboard system, i.e., an actual practical device to consume the daily waste output of one astronaut in 24 hours, electrochemical incineration of human wastes in space vehicles. One of the main objectives was to decide on the type of three dimensional or other electrode system that would suit this purpose. The various types of electrode systems which were considered for this purpose included: rotating disc electrode, micro-electrode (an array), vibrating electrode, jet electrode, and packed bed electrode. A computer code containing submodels for propane combustion, soot formation, and radiation is described. Propane combustion is represented by the minimum of either the reaction rate of a four-step chemical scheme or a turbulence mixing rate. Soot concentration is calculated using the formation submodel of Magnussen et al (1978) and a suitable oxidation submodel. Radiative transfer due to soot particles is determined assuming spherical absorbers and emitters, while that of the gas phase is computed using a discrete transfer method which solves the intensity equation along discrete rays. The code was applied to swirl stabilized propane flames and experimentally evaluated in an atmospheric chamber representing an axisymmetric step combustor, with the reactants introduced at the plane of the step. Radial profiles of gas temperature, velocity, and species

concentration were measured at several axial planes, along with axial profiles of soot volume concentration and radiative heat transfer. The results revealed a complex flow structure downstream of the nozzle. Agreement with numerical predictions is good once the flow is fully developed. The radiation submodel performs satisfactorily, but the soot submodel requires further development. Author (CISTI)

BOUNDARY-INDUCED PHASE TRANSITIONS IN EQUILIBRIUM AND NON-EQUILIBRIUM SYSTEMS
M. Henkel (Geneva Univ., Switzerland.) and G. Schuetz Aug. 1993 11 p
(DE94-608137; WIS-PH-93-73) Avail: CASI HC A03/MF A01 (US Sales Only)

Boundary conditions may change the phase diagram of nonequilibrium statistical systems like one dimensional asymmetric simple exclusion process with and without particle number conservation. Using quantum Hamiltonian approach, the model is mapped onto an XXZ quantum chain and solved using the Bethe ansatz. This system is related to a two dimensional vertex model in thermal equilibrium. The phase transition caused by a point-like boundary defect in the dynamics of the one dimensional exclusion model is in the same universality class as a continuous (bulk) phase transition of the two dimensional vertex model caused by line defect at its boundary. THE FAR-INFRARED ABSORPTION SPECTRUM OF LOW TEMPERATURE HYDROGEN GAS Ph.D. Thesis
Edward Hyman Wishnow Feb. 1993 192 p
(ISBN-0-315-85432-4; CTN-94-61158) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The far infrared spectrum of normal hydrogen gas was measured over the temperature range 21-38 K and the pressure range 0.6-3 atmospheres. The spectra cover the very weak and broad collision induced translational absorption band of H2, well isolated from the H2 rotational lines at these temperatures. To observe the weak translational absorption band, a long pathlength multireflection He-cooled absorption cell was designed and constructed. The cell is coupled to a Fourier transform interferometer and H2 spectra were obtained at a resolution of 0.24/cm. The integrated absorption of the measured H2 translational spectrum is consistent with the binary absorption coefficient calculated using the Poll and Van Kranendonk theory of collision induced absorption. No sharp spectral features were observed that can be attributed to dimer transitions. The H2 spectra show the sharp R(0) line of hydrogen deuteride (HD) superposed on the translational band at 89.2/cm, where the HD is present in the gas at natural abundance. Since the experimental conditions were close to those found in the atmospheres of Uranus and Neptune, the observed spectra have relevance to astronomical observation of H2, in particular to the determination of planetary deuterium hydrogen ratios. Spectra of other gases and gas mixtures (including He, N2, O2, CH4, CO, Ar) at 78 K and 88 K were also obtained. Author (CISTI)

In order to understand and successfully model the plasma processing used in device fabrication, it is important to determine the role played by plasma-generated radicals. The authors have used the IRIS technique (Imaging of Radicals Interacting Surfaces) to obtain the reactivity of NH(X(exp 3)S(-)) and OH(X(exp 2)P) at a silicon nitride film surface while the film is exposed to a plasma-type environment. The reactivity of NH was found to be zero both during exposure of the surface to an NH3 plasma and during active deposition of silicon nitride from a SiH4/NH3 plasma. No NH surface reaction was detectable for any rotational states of NH and over a surface temperature range of 300-700 K. OH radicals generated in an H2O plasma were found to have a reactivity of 0.57 on a room temperature oxidized silicon nitride surface. The OH reactivity falls to zero as the temperature of the substrate is raised. DOE

APPLICATION OF SEMICLASSICAL METHODS TO REACTION RATE THEORY Ph.D. Thesis
R. Hernandez Nov. 1993 147 p
(Contract DE-AC03-76SF-00098)
(DE94-007041; LBL-34925) Avail: CASI HC A07/MF A02

This work is concerned with the development of approximate methods to describe relatively large chemical systems. This effort has been divided into two primary directions: First, we have extended and applied a semiclassical transition state theory (SCTST) originally proposed by Miller to obtain microcanonical and canonical (thermal) rates for chemical reactions described by a nonseparable Hamiltonian, i.e. most reactions. Second, we have developed a method to describe the fluctuations of decay rates of individual energy states from the average RRKM rate in systems where the direct calculation of individual rates would be impossible. Combined with the semiclassical theory, this latter effort has provided a direct comparison to the experimental results of Moore and coworkers. In SCTST, the Hamiltonian is expanded about the barrier and the 'good' action-angle variables are obtained perturbatively; a WKB analysis of the effectively one dimensional reactive direction then provides the transmission probabilities. The advantages of this local approximate treatment are that it includes tunneling effects and anharmonicity, and it systematically provides a multidimensional dividing surface in phase space. The SCTST thermal rate expression has been reformulated providing increased numerical efficiency, an appealing link to conventional transition state theory, and the ability to go beyond the perturbative approximation. ANALYSIS OF INFRARED RADIATION HEATING PROCESS CONSIDERING CHEMICAL REACTION OF MATERIAL TO BE HEATED
T. Miyanaga, T. Onuma, and Y. Nakano Apr. 1993 26 p In JAPANESE
(DE94-744116; CRIE-T-92039) Avail: CASI HC A03/MF A01

A one dimensional infrared radiation heating simulation method was developed that considers chemical changes in materials to be heated. The simulation method analyzes processes to heat polyethylene glycol with far infrared radiation and near infrared radiation, and compares the results with experimental results. The analytical results indicated relatively well the trends of temperature rise in parts of a material to be heated, proving the suitability of this method as a simplified method to investigate heating internal to a material. Identical result was obtained in heating the white of an egg. As a result of using this method to calculate infrared radiation energy absorption in parts of the material being heated, it was found that heating with far infrared radiation has its energy absorbed in the vicinity of the surface of the heated material, and the trend would not change even if chemical change has been caused in the heated material. In addition, the present method can estimate complex infrared radiation heating processes in materials to be heated and the required amount of infrared ray irradiation relatively easily. The method can also be utilized for selection of infrared radiating bodies suitable for particular materials to be heated, as well as for rational designs of heating furnaces. DOE

STRUCTURAL ANALYSIS OF AMORPHOUS PHOSPHATES USING HIGH PERFORMANCE LIQUID CHROMATOGRAPHY
B. C. Sales, L. A. Boatner, B. C. Chakoumakos, J. C. McCallum, J. O. Ramey, and R. A. Zuhr 1993 13 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-004791; CONF-931108-29) Avail: CASI HC A03/MF A01

Determining the atomic-scale structure of amorphous solids has proven to be a formidable scientific and technological problem for the past 100 years. The technique of high-performance liquid chromatography (HPLC) provides unique detailed information regarding the structure of partially disordered or amorphous phosphate solids. Applications of the experimental

technique of HPLC to phosphate solids are reviewed, and examples of the type of information that can be obtained with HPLC are presented. Inorganic phosphates encompass a large class of important materials whose applications include: catalysts, ion-exchange media, solid electrolytes for batteries, linear and nonlinear optical components, chelating agents, synthetic replacements for bone and teeth, phosphors, detergents, and fertilizers. Phosphate ions also represent a unique link between living systems and the inorganic world. DOE

GROUP TRANSFER AND ELECTRON TRANSFER REACTIONS OF ORGANOMETALLIC COMPLEXES: SUMMARY OF RESEARCH ACCOMPLISHED IN 1993
1993 4 p
(Contract DE-FG02-87ER-13775)
(DE94-004963; DOE/ER-13775/5) Avail: CASI HC A01/MF A01

In the past year, the research on mechanisms of electron transfer processes between organometallic complexes has continued to progress with emphasis on two electron processes and on reactions of organometallic radicals. This summary will highlight the research on: (1) halide transfer reactions, (2) alkyl and acyl transfer reactions, and (3) reactions of seventeen-electron organometallic complexes. At this point, some conclusions on the transfer of hydrogen, halogen, and methyl as the cation, radical, and anion can be made. For each group, transfer as the cation is more facile. For hydrogen, transfer as the hydride is considerably slower, but H* transfers nearly as rapidly as H(+). Methyl could be transferred as CH3(+) or CH3(-), but not as the radical. Halogens transfer readily as X(sup +), more slowly as X* and not at all as X(-). DOE

REINTERPRETATION OF RATE DATA FOR THE REACTION OF ClF AND F2
L. D. Trowbridge Jan. 1994 12 p
(Contract DE-AC05-84OR-21400)
(DE94-005819; K/TCD-1091) Avail: CASI HC A03/MF A01

Experimental data on the rate of recombination of ClF + F2 have been reinterpreted to yield a single rate equation. This reinterpretation assumes that the recombination reaction is surface area dependent and is first order in partial pressure of each of F2 and ClF. The recombination rate equation used fits quite well three data sets which varied significantly in available NiF2 surface area. The resulting equation is dn(ClF3)/dt = A S P(F2) P(ClF) (1 - Theta) e(exp -E/RT), where dn(ClF3)/dt is the rate of formation of ClF3 in mol/s, S is the surface area of NiF2 catalyst in square centimeters, P(X) is the partial pressure of species X in Torr, R is the gas constant (1.987 cal/mol-K), and T is the temperature in Kelvin. The pre-exponential A and activation energy E are given by: A = 2.853 x 10(exp -8) mole/s-cm(exp 2)-Torr(exp 2) and E = 11,665 cal/mole. The term (1 - Theta), a product surface-coverage related inhibition factor, is given by: (1 - Theta) = (1 + 0.184 P(ClF3))(exp -1), although (1 - Theta) is never allowed to be less than 16 percent. DOE

AN INVESTIGATION OF THE REACTING VORTEX STRUCTURES ASSOCIATED WITH PULSE COMBUSTION Ph.D. Thesis
Thomas William Zsak 1993 166 p
Avail: Univ. Microfilms Order No. DA9325399

An investigation of the reacting vortex structures associated with pulsating combustion is performed using a laboratory dump combustor in order to gain an understanding of the controlling physical and chemical processes present during the burning of the vortex structures. Stabilized on the lip of a rearward-facing step flame holder, the vortices are shed at acoustic longitudinal modes of the apparatus. In all cases examined, a fuel-rich mixture of methane and air is used, 30 percent greater than stoichiometric, and the velocity at the dump plane is 21 m/sec. Results are presented for the expansion ratios of 4.0 and 12.0. A linearized one-dimensional acoustic model is developed to predict the resonant acoustic modes and mode shapes of the system for the two configurations. Heat addition is modeled as a sinusoidally varying volumetric mass source which can be placed at any location within the combustion chamber. Good agreement is found between the natural frequencies predicted by the model and those obtained experimentally under both hot- and cold-flow conditions. The effects of different combustion chamber temperatures on the pressure and velocity responses are revealed as are the effects of placing the heat addition at different axial locations downstream of the dump plane. It is shown that the pressure amplitude spectra for each expansion ratio can be successfully predicted given the relationship between heat release in the chamber and frequency. The ignition mechanisms of the vortex structures are found to be different for the two chamber configurations, and the bulk of the heat release is shown to occur much closer to the dump plane for the chamber with the smaller expansion ratio. The influence of the lower wall of the combustor on the burning of the structures is shown to be weaker for the chamber with the larger expansion ratio. The additions of ionization probes and an intensified, charge-injection-device (CID) camera to the experimental program have allowed the burning histories of the shed vortex structures to be recorded. Capturing an image of the chemiluminescence from the burning of the vortices at nearly the same instant as a shadowgraph image of the density gradients within the chamber completely describes the reacting flow field. Temperature measurements made with fine-wire thermocouples complete the experimental investigation and complement the results obtained above. Dissert. Abstr.

APPLICATION OF THE EXTENDED KALMAN FILTER TO THE ESTIMATION OF THE CHAR MASS IN A FLUIDIZED BED COMBUSTOR
Luigi Piroddi 1993 25 p Sponsored in part by Ministry of University and Scientific and Technological Research; CNR; and Ente Nazional per l'Energia Elett
(Rept-93-065; ETN-94-95825) Avail: Issuing Activity (Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milan, Italy)

Research aiming at the design of real time estimation techniques of

the mass of char starting from available Fluidized Bed Combustor (FBC) plant measurements is presented. To this purpose, the Extended Kalman Filter (EKF) was adopted as the basic estimation tool. The following subprocesses of the combustion process are described in order to develop an appropriate mathematical model of the plant: fluid dynamics, coal drying and devolatilization, char combustion, fines combustion, oxygen concentration, and energy storage and heat transfer. A model of the plant (char mass conservation equation and bed energy conservation equation) is given. An estimation oriented model is given and the char mass estimation is described. ESA

The eighth and final irradiation segment for pressurized tubes constructed from the fusion prime candidate alloy (PCA) has been completed in the Fast Flux Test Facility (FFTF). At 178 dpa and approximately 400 C, the irradiation creep of 20% cold-worked PCA has become dominated by the 'creep disappearance' phenomenon. The total diametral deformation rate has reached the limiting value of 0.33%/dpa at the three highest stress levels employed in this test. The stress-enhancement of swelling tends to camouflage the onset of creep disappearance, however, requiring the use of several nontraditional techniques to extract the creep coefficients. No failures occurred in these tubes, even though the swelling ranged from approximately 20 to approximately 40%. DOE

Beryllium is presently a leading candidate material for fusion reactor first wall coating and divertor applications. This paper reviews the literature on beryllium, emphasizing the effects of irradiation on essential properties. Swelling and embrittlement experiments as a function of irradiation temperature and dose, and as a function of neutron spectrum, are described, and the results are quantified where possible. Effects of impurity content are also reported, from which optimum composition specifications can be defined. Microstructural information has also been obtained to elucidate the processes controlling the property changes. The available information indicates that beryllium divertors can be expected to embrittle quickly and may need frequent replacement. DOE

COMPUTER SIMULATION OF MARTENSITIC TRANSFORMATIONS Ph.D. Thesis
Ping Xu Nov. 1993 198 p
(Contract DE-AC03-76SF-00098)
(DE94-005213; LBL-34908) Avail: CASI HC A09/MF A03

The characteristics of martensitic transformations in solids are largely determined by the elastic strain that develops as martensite particles grow and interact. To study the development of microstructure, a finite element computer simulation model was constructed to mimic the transformation process. The transformation is athermal and simulated at each incremental step by transforming the cell which maximizes the decrease in the free energy. To determine the free energy change, the elastic energy developed during martensite growth is calculated from the theory of linear elasticity for elastically homogeneous media, and updated as the transformation proceeds. Addition of nonmetal interstitial atoms to Zr-Ni compounds has resulted in several new phases. A single-crystal x-ray study was carried out for Zr3NiO.Zr4Ni2O is a high-temperature phase, forming in samples annealed at 1250 C. Huekel band calculations led to prediction and confirmation of additional phases in more electron rich systems. Other phases studied by XRD are Z6Ni4Ti2O(0.6), Nb6Ni6O, and Nb6Ni4Ta2O2. Phases identified by powder diffraction are Nb4Ni2O, Zr4Cu2O, and Zr6Co4Ti2O. New Zr kappa phases in space group P6s3/mmc were found: Zr9Mo4SO(x) and Zr9W4(S,Ni)O3. A new structure type was discovered with Zr6Ni6TiSiO(1.8). In all these interstitially stabilized phases, O is coordinated in Zr octahedral; there are no Ni-O interactions. DOE

(DE94-005562; IS-T-1653) Avail: CASI HC A10/MF A03

Three solid phases are involved in the phase equilibria of the intermetallic compound Ni3Al near its melting point, beta, gamma'(Ni3Al), and gamma. The generally-accepted phase diagram involves a eutectic reaction between beta' and gamma, but some recent studies agree with an older diagram due to Schramm, which has a eutectic reaction between the beta and gamma' phases. The phase equilibria near Ni3Al compositions was evaluated using quenched directional solidification experiments, that preserve the microstructures tonned at the solidification front, and using diffusion couple experiments. These experiments show that eutectic forms between beta and gamma' phases, as in the Schramm diagram. Growth and phase transformations of these three phases are also studied in the directional solidification experiments. Microstructure analysis shows that etching of Ni3Al(gamma') is very sensitive to small composition variations and crystallographic orientation changes. The eutectic solidification study confirms that the equilibrium eutectic is gamma' + beta, and that the metastable gamma + beta eutectic might be also produced in this system according to the impurities, solidification rates, and composition variations. INTERMETALLIC GROWTH AT THE INTERFACE BETWEEN COPPER AND BISMUTH-TIN SOLDER M.S. Thesis
Fred O. Vollweiler Sep. 1993 80 p
(AD-A275716) Avail: CASI HC A05/MF A01

Tin-bismuth alloys have been proposed as alternatives to lead containing solders for interconnection and packaging applications. Consequently, the interface between copper metallizations and bismuth-tin solders needs to be evaluated with respect to brittle intermetallic formation. In the binary Bi-Sn alloys, both the Cu6Sn5 and Cu3Sn intermetallic phases were found at the Cu/solder interface after exposure at 250 C, 300 C, and 350 C. Bi-Sn-Sb alloys were also studied and in addition to the aforementioned intermetallic compounds Cu-Sb intermetallics were found. Kinetic growth laws have been established for the intermetallics at various temperatures and solder compositions. In addition, bulk samples of the solder were tested in compression in the furnace-cooled and quenched condition. Quenching appeared to result in higher strain rate dependence. Furthermore the tin-rich compositions were more strain rate sensitive than the bismuth-rich composition. DTIC

EFFECTS OF THERMOMECHANICAL PROCESSING ON TENSILE AND LONG-TIME CREEP BEHAVIOR OF Nb-1 PERCENT Zr-0.1 PERCENT C SHEET
Robert H. Titran and Mehmet Uz Mar. 1994 17 p Presented at the Metallurigal Society Annual Meeting, San Francisco, CA, 27 Feb. - 3 Mar. 1994 Prepared in cooperation with DOE, Washington, DC
(RTOP 583-02-21)
(NASA-TM-106319; E-8065; NAS 1.15:106319; DOE/NASA/26310-19)
Avail: CASI HC A03/MF A01

Effects of thermomechanical processing on the mechanical properties of Nb-1 wt. percent Zr-0.1 wt. percent C, a candidate alloy for use in advanced space power systems, were investigated. Sheet bars were cold rolled into 1-mm thick sheets following single, double, or triple extrusion operations at 1900 K. All the creep and tensile specimens were given a two-step heat treatment 1 hr at 1755 K + 2 hr 1475 K prior to testing. Tensile properties were determined at 300 as well as at 1350 K. Microhardness measurements were made on cold rolled, heat treated, and crept samples. Creep tests were carried out at 1350 K and 34.5 MPa for times of about 10,000 to 19,000 hr. The results show that the number of extrusions had some effects on both the microhardness and tensile properties. However, the long-time creep behavior of the samples were comparable, and all were found to have adequate properties to meet the design requirements of advanced power systems regardless of thermomechanical history. The results are discussed in correlation with processing and microstructure, and further compared to the results obtained from the testing of Nb-1 wt. percent Zr and Nb-1 wt. percent Zr-0.06 wt. percent C alloys. The goal of this program is to provide a framework through which metallic alloy development programs and aircraft life assessment methodologies may exploit the potentially significant advantages in performance, weight reduction, and cost savings offered by quality improved materials and processes. The key performance attribute studied in this investigation is fatigue durability as identified by cracking which originates from microstructural features and grows to an inspectable dimension of economic consequences (i.e., a crack requiring diagnostic or corrective action during the operational lifetime of a part). Meeting the program objective consists of the following steps: (1) coupling historical material performance data with new data to formulate the opportunity and validate the concept, (2) quantifying the relationship between microstructure and performance, (3) synthesizing and verifying analytical models for predicting statistical fatigue response from microstructure data, and (4) developing test/evaluation protocols to facilitate technology implementation and concept scale-up to quantify payoff potential. TOUGHENING MECHANISMS IN ULTRAHIGH-STRENGTH STEELS Final Report, 1 Sep. 1989 - 31 Aug. 1993
G. B. Olson and T. Mura 1 Dec. 1993 173 p
(Contract DAAL03-89-K-0152)
(AD-A275439; ARO-27163.5-MS) Avail: CASI HC A08/MF A02

A systems approach to materials design is extended to adaptive microstructures undergoing a programmed dynamic evolution in both processing and service to achieve novel combinations of properties. Fundamental principles are developed to support rational design of high-toughness ultrahigh-strength martensitic steels of interest for advanced armor and high performance gear applications. Theoretical modelling and high resolution microanalytical experiments in the martensitic alloys address control of autocatalytic coherent precipitation to achieve efficient strengthening without embrittlement, and the controlled precipitation of

optimal stability metastable austenite for adaptive dilatant transformation plasticity tuned to crack-tip stress states for efficient interaction with strain localization processes in ductile fracture. DTIC

FUNDAMENTAL STUDIES ON THE CORROSION BEHAVIOR OF WELDMENTS IN MARINE MICROBIAL ENVIRONMENTS Annual Report, 30 Sep. 1992 - 29 Sep. 1993
R. A. Buchanan, C. D. Lundin, P. Angell, A. Kovacs, and K. K. Khan Nov. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-4116)
(AD-A275247) Avail: CASI HC A03

During the first year of this project, comprehensive literature reviews were completed in the areas of (1) weldments employed in marine applications, (2) microbially influenced corrosion (MIC) in marine environments, and (3) MIC of weldments in marine environments. Specific weldment types covering a wide range of materials were selected for MIC evaluation. Laboratory MIC evaluations were initiated on a prototype weldment (as-welded 304L stainless steel base metal, 308L filler metal) in the crevice condition. Combinations of variables were employed to enhance MIC attack of the weldment during bacterial exposures, as compared to the corrosion observed during sterile control exposures. The variables included three different consortia of marine bacteria, different degrees of solution aeration, and different solution replacement rates (dilution rates) during continuous low-flow conditions. Unfortunately, little differentiation between the bacterial and sterile-control results have been obtained to date. When corrosion occurred, either in the bacterial or control experiments, it always occurred as general or pitting-type corrosion at crevice sites within the weld-modified (weld-metal/HAZ) surface area, never within the unaffected base-metal area. Corrosion potential and solution-redox-potential measurements suggested that oxygen concentration cells contributed to the sterile-control results, but due to the uniform and highly-deaerated condition at the bacterial specimen surfaces, did not contribute to the bacterial results. CYCLIC AXIAL-TORSIONAL DEFORMATION BEHAVIOR OF A COBALT-BASE SUPERALLOY
Peter J. Bonacuse (Army Research Lab., Cleveland, OH.) and Sreeramesh Kalluri (Sverdrup Technology, Inc., Brook Park, OH.) Nov. 1992 25 p Presented at the Second Symposium on Cyclic Deformation, Fracture, and Non-Destructive Evaluation of Advanced Materials, Miami, FL, 16-17 Nov. 1992; sponsored by the American Society for Testing and Materials
(Contract NAS3-25266; RTOP 584-03-11)
(NASA-TM-106372; E-8182; NAS 1.15:106372; ARL-MR-113) Avail: CASI HC A03/MF A01

Multiaxial loading, especially at elevated temperature, can cause the inelastic response of a material to differ significantly from that predicted by simple flow rules, i.e., von Mises or Tresca. To quantify some of these differences, the cyclic high-temperature, deformation behavior of a wrought cobalt-based superalloy, Haynes 188, is investigated under combined axial and torsional loads. Haynes 188 is currently used in many aerospace gas turbine and rocket engine applications, e.g., the combustor liner for the T800 turboshaft engine for the RAH-66 Comanche helicopter and the liquid oxygen posts in the main injector of the space shuttle main engine. The deformation behavior of this material is assessed through the examination of hysteresis loops generated from a biaxial fatigue test program. A high-temperature axial, torsional, and combined axial-torsional fatigue data base has been generated on Haynes 188 at 760 C. Cyclic loading tests have been conducted on uniform gauge section tubular specimens in a servohydraulic axial-torsional test rig. Test control and data acquisition were accomplished with a minicomputer. In this paper, the cyclic hardening characteristics and typical hysteresis loops in the axial stress versus axial strain, shear stress versus engineering shear strain, axial strain versus engineering shear strain, and axial stress versus shear stress spaces are presented for cyclic, in-phase and out-of-phase, axial torsional tests. For in-phase tests three different values of the proportionality constant, lambda (ratio of engineering shear strain amplitude to axial strain amplitude), are examined, viz., 0.86, 1.73, and 3.46. In the out-of-phase tests, three different values of the phase angle, phi (between the axial and engineering shear strain waveforms), are studied, viz., 30, 60, and 90 deg with lambda = 1.73. The cyclic hardening behaviors of all the tests conducted on Haynes 188 at 760 C are evaluated using the von Mises equivalent stress-strain and the maximum shear stress-maximum engineering shear strain (Tresca) curves. Comparisons are also made between the hardening behaviors of cyclic axial, torsional, and combined in-phase and out-of-phase axial-torsional fatigue tests. These comparisons are accomplished through simple Ramberg-Osgood type stress-strain functions for cyclic, axial stress-strain and shear stress-engineering shear strain curves. Author (revised)

REPORT ON SMART MATERIALS [RAPPORT: MATERIAUX INTELLIGENTS]
F. Garnier 29 May 1992 38 p In FRENCH Sponsored by Direction des Recherches, Etudes et Techniques and Centre de Documentation de l'Armenebt
(PB94-137528) Avail: Issuing Activity (National Technical Information Service (NTIS))

Smart materials are defined as complex materials able to function as sensors (for detecting physical or chemical changes inside or outside the material), data-transfer and -processing devices (for responding to outside changes), and actuators (enabling the material to modify itself or the physical or chemical environment around it). Despite widespread use of the term, a review of the literature shows that, strictly speaking, no such materials exist. The author believes the value of the smart materials concept lies in the joint development of a set of themes by physicists, chemists, biologists, computer specialists and mathematicians, which can be used to advance materials toward real possession of multiple functions. RESEARCH ON THE IMPROVEMENT OF SHAPE-MEMORY AND MAGNETOSTRICTIVE MATERIALS Report, 1 Aug. 1989 - 31 Jul. 1993
Richard D. James 13 Oct. 1993 5 p
(Contract DAAL03-89-G-0081)
(AD-A275397; ARO-27063.12-MA-SM) Avail: CASI HC A01/MF A01

The goals of this research are to give predictive, quantitative models that can be used to improve shape-memory and magnetostrictive materials, and that can guide the development of new materials. A new theory of martensite and a new theory of magnetostriction were found, both of which predict accurately observed domain structures in these alloys. The principal findings based on these theories are (1) the importance of the precise values of the lattice parameters in determining the microstructure, and therefore the behavior of these materials; (2) the presence of the growth twins in Tb(x)Dy(1-x)Fe2, the material with the largest known magnetostriction, do not decrease the magnetostrictive strain in this alloy, as was formerly thought; (3) thermoelastic theory gives a mechanism for increased strain-rate dependence in uniaxial tension experiments on TiNi. A unique experimental facility was built for fundamental experimental studies on stress and magnetic field-induced phase transformation. DTIC

The breakdown of native and anodically-grown oxide films on Ti electrodes is investigated by scanning electrochemical microscopy (SECM), video microscopy, transmission electron microscopy, and voltammetry. SECM is used to demonstrate that the oxidation of Br(-) on Ti occurs at microscopic surface sites (10 to 50 micrometer diameter, 30 sites/sq cm) that are randomly positioned across the oxide surface. After determining the position of the active sites for Br(-) oxidation, breakdown of the oxide is initiated by increasing the electrode potential to more positive values. Direct correspondence is observed between the location of the electroactive sites and corrosion pits, indicating that oxide breakdown is associated with a localized site of high electrical conductivity. The potential at which pitting is observed in voltammetric experiments is found to be proportional to the average oxide thickness, for values ranging between 20 and 100 A, indicating that breakdown is determined either by the magnitude of the electric field within the oxide or by the interfacial potential at the oxide/Br(-) solution interface. Pitting occurs at significantly lower potentials in Br(-) solutions than in Cl(-) solutions, suggesting a strong chemical interaction between the TiO2 surface and Br(-). A mechanism of oxide breakdown is proposed that is based on the potential-dependent chemical dissolution of the oxide at microscopic surface sites. DTIC

The electrochemical behavior of sputter-deposited nonequilibrium stainless aluminum alloys and different methods to produce bulk or thick-film material have been investigated. Nonequilibrium Al-Ta and Al-W alloys exhibit enhanced passivity over a wide pH range even though the passive film chemistry varies considerably. This enhanced passivity can be explained by the solute-rich interphase mechanism (SRIM) which states that formation and passivation of occluded cells stabilize the passive film from continued Cl(-) attack and dissolution. The best material is produced by sputter deposition; however, physical vapor deposited and plasma sprayed material also exhibit some enhanced passivity. DTIC

(AD-A275400; ARO-29728.1-MS-AAS) Avail: CASI HC A01

When two-phase mixtures of ductile metals are mechanically alloyed, they often assume a convoluted lamellar structure. Since these powders are consolidated at elevated temperatures, their structures (and therefore properties) are likely be altered by consolidation processing. We have investigated microstructural changes that take place upon heat-treating mechanically alloyed Cu-20 vol.% NB alloys. The transition from a plate-like to a spherical microstructure is described, and the kinetics of this process appear controlled by a type of boundary diffusion even though the coarsening temperature was high in terms of the homologous temperature of Cu. Reasons for this behavior are suggested. Finally, during heat treatment (carried out in hydrogen), a Nb layer forms around the particles. The thickness of this layer (and the corresponding zone denuded of Nb within the particle) increases with continued elevated temperature exposure at a rate that is consistent with the process being driven by curvature forces. CHAMBER FREE FUSION WELDING ROOT SIDE PURGING METHOD AND APPARATUS Patent Application
William F. McGee, inventor (to NASA) (Martin Marietta Space Systems, Inc., Huntsville, AL.) and Daniel J. Rybicki, inventor (to NASA) (Martin Marietta Space Systems, Inc., Huntsville, AL.) 29 Nov. 1993 14 p
(NASA-Case-MFS-28832-1; NAS 1.71:MFS-28832-1;
US-Patent-Appl-SN-158331) Avail: CASI HC A03/MF A01

A method and apparati are presented for non-chamber root side purging in fusion welding of oxygen reactive metals which require that the molten weld zone and local solid areas of the weld seam remaining at high temperatures be shielded from normal atmosphere to prevent degradation of the welded area. The apparati provide an inert atmosphere to the root side of a weld joint through a porous medium whereby the jet-like thrust of the plasma arc actually draws the continuously supplied inert atmosphere into the path of the molten or high temperature solid weld zone. The porous medium is configured so it can be placed at the borders of the weld seam and substantially parallel to the seam without restricting the view of the root side of the seam. The inert gas is dispersed evenly through the porous media and across the weld seam, at the point of arc penetration and in front of and behind the arc. The apparati can be constructed so as to limit the amount of inert gas flow and can be mobile and travel synchronously with the welding arc. NASA

The research project was commenced in order to obtain a deeper understanding of the basic phenomena behind the effect of inclusions on the machinability of steel and, particularly, of the prerequisites and mechanisms of the formation of a protective layer by the inclusions on the cutting tool during machining of steel. The main object of the research work was to find new types of inclusions with which the machinability of steel could be improved without any deterioration of its mechanical properties. NTIS

THE SYNTHESIS AND STRUCTURAL CHARACTERIZATION OF Na3WO3N Technical Report, 1990 - 1993

S. H. Elder, F. J. DiSalvo, J. B. Parise, J. A. Hriljac, and J. W. Richardson, Jr. 17 Jan. 1994 24 p
(Contract N00014-91-J-1269)
(AD-A275243; TR-18) Avail: CASI HC A03/MF A01

We report the discovery of a new ternary oxynitride, Na3WO3N. Na3WO3N is synthesized by exposing a eutectic melt consisting of 1/2Na2O: 1Na2WO4 to a flow of ammonia gas at 695 C. The compound crystallizes in the acentric space-group Pmn2(1) with a = 7.2481 (3), b = 6.2728 (3) and c = 5.6493 (2) A. The structure was determined from synchrotron X-ray powder diffraction data and refined using the Rietveld analysis on neutron powder diffraction data. It is isostructural to the low temperature form of Li3PO4, which can be derived from an ordered wurtzite structure-type with all the atoms having tetrahedral coordination. Alternatively, the structure can be described as being 'salt-like' consisting of isolated (WO3N)(-3) tetrahedral poly-anions separated by Na(+). DTIC

ROTARY ACTUATOR Patent Application
Myron Brudnicki, inventor (to NASA) (Allied-Signal Corp., Morristown, NJ.) 12 Oct. 1993 12 p
(NASA-Case-MFS-28581-1; NAS 1.71:MFS-28581-1;
US-Patent-Appl-SN-134441) Avail: CASI HC A03/MF A01

Rotary actuators and other mechanical devices incorporating shape memory alloys are provided herein. Shape memory alloys are a group of metals which when deformed at temperatures below their martensite temperatures, resume the shapes which they had prior to the deformation if they are heated to temperatures above their austensite temperatures. Actuators in which shape memory alloys are employed include bias spring types, in which springs deform the shape memory alloy (SMA), and differential actuators, which use two SMA members mechanically connected in series. Another type uses concentric cylindrical members. One member is in the form of a sleeve surrounding a cylinder, both being constructed of shape memory alloys. Herein two capstans are mounted on a shaft which is supported in a framework. Each capstan is capable of rotating the shaft. Shape memory wire, as two separate lengths of wire, is wrapped around each capstan to form a winding around that capstan. The winding on one capstan is so wrapped that the wire is in a prestretched state. The winding on the other capstan is so wrapped that the wire is in a taut, but not a prestretched, state. Heating one performs work in one direction, thus deforming the other one. When the other SMA is heated the action is reversed. NASA

A thermal barrier coating system consists of two layers of a zirconia-yttria ceramic. The first layer is applied by low pressure plasma spraying. The second layer is applied by conventional atmospheric pressure plasma spraying. This facilitates the attachment of a durable thermally insulating ceramic coating directly to the surface of a highly oxidation resistant NiAl-based intermetallic alloy after the alloy has been preoxidized to promote the formation of a desirable Al2O3 scale.

A method for estimating the feasibility of metal alloy microanalysis and the possible analytical performances are investigated. The aim is the optimization of the equipment's use and costs. Moreover, the procedure is a decision making tool concerning analysis orientation and feasibility. The principles of scanning electron microscopy are given, together with the device description. Possible applications of scanning electron microscopy on qualitative and quantitative analysis are summarized. X-ray emission spectra and equipment parameters are characterized. ESA

Gamma-ray spectra obtained from samples flown aboard the Long Duration Exposure Facility have been analyzed to obtain the nuclear species produced in this material by the interaction of this material with protons and neutrons in this material by the interaction of this material with protons and neutrons encountered in its 69 month orbital flight as well as to quantify the specific activity (pCi/kg) of these nuclear species. This quantification requires accurate corrections of efficiency, self-attenuation, and background. Plans have been developed for archival of the spectra in a form readily accessible to the scientific, engineering and technical community engaged in space research and application. Work has been initiated in the process of estimating the flux of activating particles encountered by material at various locations of the spacecraft.

THE EFFECT OF VARIOUS METALLURGICAL PARAMETERS ON THE FLOW AND FRACTURE BEHAVIOR OF POLYCRYSTALLINE NiAl NEAR THE BRITTLE-TO-DUCTILE TRANSITION
Ronald D. Noebe Apr. 1994 254 p
(RTOP 505-63-52)
(NASA-TM-106534; E-8669; NAS 1.15:106534) Avail: CASI HC A12/MF A03

An investigation of the effect of various metallurgical parameters such as interfaces, allowing additions, test temperature, and strain rate on the flow and fracture behavior of polycrystalline NiAl is summarized. From this study, a more complete understanding of the deformation and fracture behavior of polycrystalline NiAl near the brittle-to-ductile transition temperature has been developed. A mechanism for the BDTT is proposed that is based on the operation of localized dislocation climb processes that operate within the vicinity of the grain boundaries and provide the additional deformation mechanisms necessary for grain-to-grain compatibility during plastic deformation. Finally, methods for improving the low temperature mechanical behavior of NiAl were considered and reviewed within the context of the present knowledge of NiAl-based materials and the operative deformation and fracture mechanisms determined in this study. Special emphasis was placed on the use of second phases for improving low temperature properties. Author (revised)

THE EFFECT OF MECHANICAL PAINT STRIPPING ON THE FATIGUE AND FRACTURE OF THIN ALUMINUM AIRPLANE SKIN Ph.D. Thesis
Joe P. Amro 1992 150 p
Avail: Univ. Microfilms Order No. DA9311975

An experimental investigation has been carried out to evaluate the affects of dry stripping (paint removal by plastic particle blasting) on aluminum aircraft skins (2024-T3). Analytical procedures were carried out for determining changes in fatigue life and relevant fracture resistance parameters such as number of cycles required to generate a surface crack of certain length, crack propagation rate, and number of cycles to failure while indicating the dependence of these parameters on the surface condition (morphology). The surface morphology dependence on deformation, fracture resistance properties, and defects presented on the surface were characterized using scanning electron microscopy, optical microscopy, and other modern metallographic techniques. The results indicated that all the parameters of plastic media blasting had significant effects on the fatigue life of the specimens. Minor changes in the blasting parameters may reveal different results. All fatigue samples were found to

exhibit a general decrease in life of 10 to 46 percent after being subjected to four cycles of paint removal. The samples were cyclically loaded to 20,000 cycles then stripped and repainted four times; 20,000 cycles represents approximately 5 years of life. The initial stress ratio for loading was 0.1 with stresses varying from 20 to 65 ksi. Dissert. Abstr.

FIRST PRINCIPLES PSEUDOPOTENTIAL CALCULATIONS ON ALUMINUM AND ALUMINUM ALLOYS
J. W. Davenport, N. Chetty, R. B. Marr, S. Narasimhan, J. E. Pasciak, R. F. Peierls, and M. Weinert 1993 10 p Presented at the Fall Meeting of the Minerals, Metals and Materials Society: Physical Metallurgy and Materials, Pittsburgh, PA, 17-21 Oct. 1993
(Contract DE-AC02-76CH-00016)
(DE94-004890; BNL-49718; CONF-931009-18) Avail: CASI HC A02/MF A01

Recent advances in computational techniques have led to the possibility of performing first principles calculations of the energetics of alloy formation on systems involving several hundred atoms. This includes impurity concentrations in the 1% range as well as realistic models of disordered materials (including liquids), vacancies, and grain boundaries. The new techniques involve the use of soft, fully nonlocal pseudopotentials, iterative diagonalization, and parallel computing algorithms. Here the authors give a review of recent results using parallel and serial algorithms on metallic systems including liquid aluminum and liquid sodium and also new results on vacancies in aluminum and on aluminum-magnesium alloys. LOGISTICS FOR THE IMPLEMENTATION OF LEAD-FREE SOLDERS ON ELECTRONIC ASSEMBLIES
P. T. Vianco and I. Artaki 1993 18 p Presented at the International Waste Management Conference, San Juan, Puerto Rico, 28 Apr. - 1 May 1993
(Contract DE-AC04-94AL-85000)
(DE94-004800; SAND-93-0226C; CONF-9304117-6) Avail: CASI HC A03/MF A01

The prospects of legislative and regulatory action aimed at taxing, restricting, or banning lead-bearing materials from manufactured products has prompted the electronics community to examine the implementation of lead-free solders to replace currently used lead-containing alloys in the manufacture of electronic devices and assemblies. The logistics for changing the well established 'tin-lead solder technology' require not only the selection of new compositions but also the qualification of different surface finishes and manufacturing processes. The meniscometer/wetting balance technique was used to evaluate the wettability of several candidate lead-free solders as well as to establish windows on processing parameters so as to facilitate prototype manufacturing. Electroplated and electroless Sn-100 coatings, as well as organic preservatives, were also examined as potential alternative finishes for device leads and terminations as well as circuit board conductor surfaces to replace traditional tin-lead layers. Sandia National Laboratories and AT&T have implemented a program to qualify the manufacturing feasibility of surface mount prototype circuit boards using several commercial lead-free solders by infrared reflow technology. ELECTROMAGNETIC EFFECT ON TURBULENT TRANSPORT IN LIQUID METALS AND ELECTROLYTES (BATH)
L. Gu and S. T. Johansen 23 Aug. 1993 36 p
(PB94-138450; STF34-A93169) Avail: Issuing Activity (National Technical Information Service (NTIS))

In order to investigate the effect of an applied magnetic field on the turbulence as well as the heat transfer in the liquid metal flow, the FLUENT computer code has been modified. In addition, a generalized model for the turbulent heat (mass) - flux has been added. Numerical simulations have been carried out in the fluid flow of a channel. It was found that the magnetic field affects the fluid flow by decreasing the turbulent viscosity. The temperature distribution is thus influenced as the turbulent enthalpy transport is decreased by an increased magnetic flux density. In the case of an applied magnetic field a lower turbulent viscosity is computed by the Reynolds stress turbulence model. Thus the heat transfer in the fluid is affected by decreasing the heat loss to the wall. These effects seem to be more pronounced at high magnetic flux density. In the case of aluminum reduction cells a present magnetic field seems to have a modest influence on the turbulent transport. NTIS

NEW INOCULANTS FOR DUCTILE CAST IRON Progress Report No. 1
A. O. Kluken and O. Grong 5 Jul. 1993 40 p
(PB94-138476; STF34-A93136) Avail: Issuing Activity (National Technical Information Service (NTIS))

The present report summarizes the activities during the project period from January through June 1993. The report is divided into two parts: Part I, Development of Inoculants, and Part II, Evaluation of Inoculation Effect. Four different non-metallic phases (i.e., silicon oxide, SiO2, iron oxide, Fe2O3, calcium silicate, CaOSiO2, and silicon carbide, SiC) were added to the inoculant melts. Foundrisil was chosen as base material for these initial tests due to its relatively high content of reactive trace elements, i.e., calcium and barium. Two of the produced inoculants showed promising oxygen 'yields' (i.e., Foundrisil containing Fe2O3, and CaOSiO2, respectively). In addition to these, pure Foundrisil and Foundrisil containing SiC were used in the foundry experiments. Metallographic examinations of the cast materials revealed that addition of iron oxide to Foundrisil increased the graphite nodule density by 45% in 5 mm section size material and by approximately 30% in 30 mm section size material, compared to pure Foundrisil. However, the increased graphite nodule density was not accompanied by an increased number density of non-metallic inclusions. Consequently, further experiments are required to clarify this inconsistency. NTIS

MELT FLOW DURING ALLOY SOLIDIFICATION: DIMENSIONAL ANALYSIS AND MODEL PROBLEMS
E. Haug and H. J. Thevik 8 Sep. 1993 50 p Sponsored by Royal Norwegian Council for Scientific and Industrial Research, Oslo, Norway
(PB94-138625; STF33-A93019) Avail: Issuing Activity (National Technical Information Service (NTIS))

A set of mechanistic equations describing melt flow during alloy solidification is transformed to a dimensionless form. How to choose appropriate scales are discussed, appropriate dimensionless groups are suggested, and the dominating terms in the equations are identified. Some comments on numerical solution procedures are given. Two classes of simplified model problems are then presented. The first class of problems focuses on the melt flow resulting from solidification shrinkage, and the second class addresses density driven melt transport due to thermal and specie concentration gradients. THE ORGANOMETALLIC CHEMICAL VAPOR DEPOSITION OF TRANSITION METAL CARBIDES: THE USE OF HOMOLEPTIC ALKYLS
M. D. Healy (Los Alamos National Lab., NM.), D. C. Smith (Los Alamos National Lab., NM.), R. W. Springer (Los Alamos National Lab., NM.), R. R. Rubiano (Massachusetts Inst. of Tech., Cambridge.), and J. E. Parmeter 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-005577; SAND-93-4079C; CONF-931108-49) Avail: CASI HC A02/MF A01

The organometallic chemical vapor deposition of transition metal carbides (M = Ti, Zr, Hf, and Cr) from tetraneopentyl-metal precursors has been carried out. Metal carbides can be deposited on Si, Al2O3, and stainless steel substrates from M(CH2C(CH3)3)4 at temperatures in the range of 300 to 750 C and pressures from 10(exp -2) to 10(exp -4) Torr. Thin films have also been grown using a carrier gas (Ar, H2). The effects of variation of the metal center, deposition conditions, and reactor design on the resulting material have been examined by SEM, XPS, XRD, ERD and AES. Hydrocarbon fragments generated in the deposition chamber have been studied by in-situ mass spectrometry. Complementary studies examining the UHV surface decomposition of Zr(CH2C(CH3)3)4 have allowed for a better understanding of the mechanism leading to film growth. DOE

FATIGUE OF CARBON AND LOW-ALLOY STEELS IN LWR ENVIRONMENTS
O. K. Chopra, W. F. Michaud, and W. J. Shack Oct. 1993 23 p Presented at the Water Reactor Safety Information Meeting, Bethesda, MD, 25-27 Oct. 1993
(Contract W-31-109-eng-38)
(DE94-005116; ANL/ET/CP-80135; CONF-931079-16) Avail: CASI HC A03/MF A01

Fatigue tests have been conducted on A106-Gr B carbon steel and A533-Gr B low-alloy steel to evaluate the effects of an oxygenated-water environment on the fatigue life of these steels. For both steels, environmental effects are modest in PWR water at all strain rates. Fatigue data in oxygenated water confirm the strong dependence of fatigue life on dissolved oxygen (DO) and strain rate. The effect of strain rate on fatigue life saturates at some low value, e.g., between 0.0004 and 0.001%/s in oxygenated water with approximately 0.8 ppm DO. The data suggest that the saturation value of strain rate may vary with DO and sulfur content of the steel. Although the cyclic stress-strain and cyclic-hardening behavior of carbon and low-alloy steels is distinctly different, the degradation of fatigue life of these two steels with comparable sulfur levels is similar. The carbon steel exhibits pronounced dynamic strain aging, whereas strain-aging effects are modest in the low-alloy steel. Environmental effects on nucleation of fatigue crack have also been investigated. The results suggest that the high-temperature oxygenated water has little or no effect on crack nucleation. DOE

NANOSIZE METAL ALLOY PARTICLE FORMATION IN Ag AND Cu SEQUENTIALLY IMPLANTED SILICA
R. A. Zuhr, R. H. Magruder, III, T. A. Anderson, and J. E. Wittig Dec. 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-005592; CONF-931108-50) Avail: CASI HC A02/MF A01

A series of high purity silica samples were sequentially implanted with Ag and Cu ions at energies such that the depth distributions for each of the ions overlap. The samples were characterized by RBS, TEM, and optical spectroscopy. Optical response was found to be dependent on order of sequential implantation as well as relative concentration of implanted elements. The changes in the optical response are attributed to composition changes of the metal colloids that are formed as a result of alloying of the sequentially implanted metal ions, as well as to changes in the size the colloids. NON-CHROMATE TALC CONVERSION COATINGS FOR ALUMINUM
R. G. Buchheit, C. A. Drewien, J. L. Finch, and G. E. Stoner 1994 13 p Presented at the Corrosion 1994: National Association of Corrosion Engineers (NACE) International Annual Conference, Baltimore, MD, 28 Feb. - 4 Mar. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005281; SAND-93-2533C; CONF-940222-10) Avail: CASI HC A03/MF A01

A method was developed for applying an inorganic conversion coating. The process is similar to chromate conversion coating methods; however, this method does not use or involve hazardous/toxic chemicals. The coating forms by precipitation involving Al(3+) Li(+), OH(-), CO3(2-), and possibly other anions. This polycrystalline coating is continuous, conformal, and persistent in aggressive environments. Coating thicknesses range from several tenths to ten micrometers. Although the outer portions of the coating are porous, the pores do not penetrate to the substrate interface. These coatings do not match the levels of performance offered by commercially available chromate conversion coatings, but are capable of meeting many of the corrosion resistance, electrical resistivity, and paint adhesion requirements established in MIL-C-5541E 'Chemical Conversion Coatings on Aluminum and Aluminum Alloys.' In this paper, methods for producing the talc coating on aluminum alloys 1100 and 6061-T6 are described and compared to traditional chromate conversion coating methods. The resulting coating structure and composition are described. Performance data for the talc coatings in MIL-C-5541E required tests are presented along with the data for commercial chromate-based coatings. DOE

INDUCED CRYSTALLIZATION IN CW LASER-IRRADIATED SOL-GEL DEPOSITED TITANIA FILMS
G. J. Exarhos and N. J. Hess 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC06-76RL-01830)
(DE94-006527; PNL-SA-22790; CONF-931108-72) Avail: CASI HC A02/MF A01

Isothermal annealing of amorphous TiO2 films deposited from acidic sol-gel precursor solutions results in film densification and concomitant increase in refractive index. Subsequent heating above 300C leads to irreversible transformation to an anatase crystalline phase. Similar phenomena occur when such amorphous films are subjected to focused cw laser irradiation. Controlled variations in laser fluence are used to densify or crystallize selected regions of the film. Low fluence conditioning leads to the evolution of a subtle nanograin-size morphology, evident in AFM images, which appears to retard subsequent film crystallization when such regions are subjected to higher laser fluence. Time-resolved Raman spectroscopy has been used to characterize irradiated regions in order to follow the crystallization kinetics, assess phase homogeneity, and evaluate accompanying changes in residual film stress. The quasichemical model is used to explain the free energy of mixing, heat of mixing, excess entropy of mixing and chemical short range order parameter for potassium-tellurium as a function of concentration. The study reveals that the constituent metals of these alloys undergo major structural changes in atomic and electronic character on alloying. The concentration dependent behaviour of thermodynamic properties on mixing occurs due to preferential ordering of unlike atoms as nearest neighbors which could simultaneously be understood within the complex formation model. An analysis of the results further suggests that heterocoordination with the formation of K2Te3 is likely to exist in the melt. It is concluded that a reasonable degree of chemical order may exist in the whole concentration range being greatest at about 50 percent at K. DOE

REALTIME STRUCTURAL ELECTROCHEMISTRY OF PLATINUM CLUSTERS USING DISPERSIVE XAFS
P. G. Allen, S. D. Conradson, M. S. Wilson, S. Gottesfeld, and I. D. Raistrick 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE94-005093; LA-UR-93-4428; CONF-931108-46) Avail: CASI HC A02/MF A01

Chemical reference tables state that the standard potential for the reaction of Pt with water, Pt + 2H2O yeilds Pt(OH)2 + 2H(+) + 2e(-), is 0.98 V, and electrochemical studies propose that this reaction may occur at potentials as low as 0.8 V. Using dispersive x-ray absorption fine-structure (XAFS) spectroscopy, the authors have directly probed the structural evolution of a Pt catalyst operating in-situ in a polymer electrolyte fuel cell during cyclic voltammetry. The changes in the number of Pt and O nearest-neighbors and the Pt charge demonstrate a close correspondence with features in the voltammogram. Because dispersive XAFS is very sensitive to detecting structural changes, they have been able to detect the presence of chemisorbed oxygen at potentials of 0.6-0.9 V in the anodic sweep. Since double-layer charging is regarded as the only process in this region for bulk Pt, these results may reflect a limitation of previous (indirect) studies on Pt electrochemistry, or they may indicate that these clusters are different from their bulk metal counterparts. Exploiting the time-resolving capability of dispersive XAFS, they also monitored changes in the Pt charge and the number of O and Pt nearest-neighbors during the electrochemical oxidation and reduction of the Pt clusters in real-time. The results are inconsistent with those expected from the place-exchange mechanism for the formation of the surface oxide on bulk Pt electrodes in aqueous solution; Pt(sub red) (k sub 1) yields Pt(submonolayer O) (k sub 2) yields PtO(x) (place exchanged Pt and O atoms: k(sub 1) much greater than k(sub 2)). Their current model for understanding these behaviors is that, relative to bulk Pt, unusual types of surface sites play a major role in determining the reactivity of these clusters. DOE

LOCALIZATION IN PRESENCE OF MAGNETIC FIELD IN 2-D DISORDERED BINARY ALLOYS
A. Brezini and N. Zekri Aug. 1993 14 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-608093; IC-93/253) Avail: CASI HC A03 (US Sales Only)

The conductance fluctuations in the presence of a magnetic field B for a disordered binary alloy are numerically examined. The Hamiltonian is quite different from the Anderson model. We calculate the participation ration for finite systems in the whole range spectrum to discriminate the nature of eigenstates. We then evaluate the conductivity from the usual Kubo Greenwood formula. The fluctuations are therefore extracted as a function of energy for a given value of B and system size L. The data predict a delocalization of the eigenstates due to the magnetic field and a factor of 2 reduction of the universal conductance fluctuations in agreement with the theory. DOE

VOLUME AVERAGED MODEL FOR THE MECHANICS OF ALLOYS SOLIDIFICATION
H. J. Thevik 30 Jun. 1993 40 p Sponsored by Royal Norwegian Council for Scientific and Industrial Research, Oslo, Norway
(PB94-138617; STF28-A93053) Avail: Issuing Activity (National Technical Information Service (NTIS))

A volume averaged mathematical model for macroscopic transport of mass, momentum, energy and species during alloy solidification is established. Details concerning the volume averaging technique are discussed and applied to the one-phase balance and interfacial transfer equations. This yields a macroscopic set of balance equations which constitutes the basis for deriving a simplified model for solidification of a binary alloy in an impermeable two dimensional enclosure. In deriving the equations, constitutive laws, thermodynamic relations, topological, and closure relations are thoroughly discussed. The report concludes with a closed set of transport equations, together with a complete list of the employed simplifications. NTIS

GENERALIZED AUGMENTED SPACE THEOREM FOR CORRELATED DISORDER AND CLUSTER COHERENT POTENTIAL APPROXIMATION
A. Mookerjee and R. Prasad Sep. 1993 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-608110; IC-93/286) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

We present a method for calculating the electronic structure of disordered alloys with short range order (SRO) which guarantees positive density of states for all values of the SRO parameter. The method is based on the generalized augmented space theorem which is valid for alloys with SRO. This theorem is applied to alloys with SRO in the tight-binding linear muffin-tin orbital (TB-LMTO) framework. This is done by using the augmented space formulation of Mookerjee and cluster coherent potential approximation. As an illustration, the method is applied to a single band mode TB-LMTO Hamiltonian. We find that the SRO can induce substantial changes in the density of states. DOE

PIT INITIATION ON PASSIVATED METAL SURFACES: CRYSTALLOGRAPHIC ORIENTATION AND ENVIRONMENTAL EFFECTS Ph.D. Thesis
Ruijin Guo Sep. 1993 224 p
(ISBN-0-315-85433-2; CTN-94-61159) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The susceptibility to pitting corrosion of Sn and Zn was found to depend on the crystallographic orientation of the surface in chloride solutions. The critical pitting potentials for Zn and Al were found to be lower in chloride solutions than in bromide solutions. The effects of the solution pH, the presence of buffers, and the halide ion species on the pitting of polycrystalline Ni were investigated in 1-molar halide solutions. It was found that the critical pitting potential (Ecp) was independent of the pH of unbuffered solutions in the 4.5-10.5 pH region. However, Ecp was greatly increased at pH 12.5, and pitting corrosion was totally retarded at pH 14 in 1-molar NaCl solution. Adding Na2CO3/NaHCO3 or Na3PO4/Ha2HPO4 buffer to the pH 10.5 solution raised the critical pitting potential of Ni. Furthermore, Ecp was lower in chloride solution than in bromide solution. Using thermodynamic data for halide complexes, potential-pH and halide concentration /pH diagrams were constructed for H2O- halide- (Sn,Zn,Al,Ni) systems. With increasing halide concentration, the formation of halide complexes is thermodynamically favored and the zone of passivity is diminished. A pitting theory is proposed which emphasizes the change in local solution chemistry and formation of halide complexes during pit initiation. This theory accounts for many effects observed. DIRECTIONAL SOLIDIFICATION CHARACTERISTICS OF HYPER-EUTECTIC Al-Cu ALLOYS UNDER VARYING GRAVITY CONDITIONS M.S. Thesis
Hong Yu 1993 191 p
(ISBN-0-315-86108-8; CTN-94-61180) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A three-zone gradients freeze furnace was specially designed to carry out unidirectional solidification on the ground as well as aboard the space shuttle. The microstructure of Al-Cu alloys was studied and the faceting behavior of the primary Al2Cu theta phase was examined as a function of alloy composition and growth rate. Solidification in microgravity promoted dendrite growth due to lack of convection. The spacings of the primary theta phase and the inter theta phase lamellar eutectic were investigated. It is concluded that the viscous stress due to natural convection disturbs the atoms, not allowing them to incorporate into crystals. Furthermore, the physical motion of nucleation sites due to natural convection may provide more nuclei for growth of theta phase particles. The segregation phenomena of hyper-eutectic Al-Cu alloys was also studied in both vertical and horizontal unidirectional solidification in unit gravity and in microgravity. Lack of convection in microgravity allowed large dendrites to grow, and solidification shrinkage is compensated mostly by deformation of the ingot rather than by interdendritic fluid flow. In ground-based samples, the gravity effect is more pronounced in the case of vertical upwards solidification.

The general principles of computer program MODA have been described allowing Monte Carlo simulation of an atom-solid interaction for incident energies from 50 eV to 10 keV. It is shown that special selection of some model parameters using experimental data permits the simulation of primary particles, sputtering of metal, and a desorption of adsorbed layers on surfaces. Also report are calculation data of hydrogen reflection and sputtering at an interaction of hydrogen atoms at initial energies from 50 to 500 eV with polycrystalline and amorphous molybdenum, containing adsorbed and penetrated hydrogen.

STUDIES OF HIGH TEMPERATURE TERNARY PHASES IN MIXED-METAL-RICH EARLY TRANSITION METAL SULFIDE AND PHOSPHIDE SYSTEMS Ph.D. Thesis
G. A. Marking Jan. 1994 239 p
(Contract W-7405-eng-82)
(DE94-006034; IS-T-1646) Avail: CASI HC A11/MF A03

Investigations of ternary mixed early transition metal-rich sulfide and phosphide systems resulted in the discovery of new structures and new phases. A new series of Zr and Hf--group V transition metal--sulfur kappa-phases was synthesized and crystallographically characterized. When the group V transition metal was Nb or Ta, the unit cell volume was larger than any previously reported kappa-phase. The presence of adventitious oxygen was determined in two kappa-phases through a combination of neutron scattering and X-ray diffraction experiments. A compound Hf10Ta3S3 was found to crystallize in a new-structure type similar to the known gamma brasses. This structure is unique in that it is the only reported 'stuffed' gamma-brass type structure. The metal components, Hf and Ta, are larger in size and more electropositive than the metals found in normal gamma brasses (e.g. Cu and Zn) and because of the larger metallic radii, sulfur can be incorporated into the structure where it plays an integral role in stabilizing this phase relative to others. X-ray single-crystal, X-ray powder, and neutron powder refinements were performed on this structure. A new structure was found in the ternary Nb-Zr-P system which has characteristics in common with many known early transition metal-rich sulfides, selenides, and phosphides. This structure has the simplest known interconnection of the basic building blocks known for this structural class. Anomalous scattering was a powerful tool for differentiating between Zr and Nb when using Mo K(alpha) X-radiation. The compounds ZrNbP and HfNbP formed in the space group Prima with the simple Co2Si structure which is among the most common structures found for crystalline solid materials. Solid solution compounds in the Ta-Nb-P, Ta-Zr-P, Nb-Zr-P, Hf-Nb-P, and Hf-Zr-S systems were crystallographically characterized. The structural information corroborated ideas about bonding in metal-rich compounds.

AN INVESTIGATION OF THE CORROSION PROPERTIES OF ALUMINUM-TANTALUM ALLOYS USING ELECTROCHEMICAL IMPEDANCE SPECTROSCOPY AND LOCAL ELECTROCHEMICAL IMPEDANCE SPECTROSCOPY Ph.D. Thesis
Robert Scott Lillard 1993 119 p
Avail: Univ. Microfilms Order No. DA9313391

An investigation of passivity of single phase Al-Ta alloys and the contribution of the second phase, Al3Ta, to breakdown is presented. In 0.1M NaCl buffered to pH 7 with boric acid and sodium borate the passive current density of pure aluminum was found to be approximately 0.3 microamps/cm(exp 2), the passive current densities of Al 4 at percent Ta, Al 8 at percent Ta were found to be 2.5 and 2.4 microamps/cm(exp 2) respectively while the pitting potentials of these alloys were approximately 500 mV greater than that of pure aluminum. Traditional EIS measurements in 0.5M boric acid 0.05M sodium borate solution found the impedance values of the Al-4Ta and Al-8Ta were found to be 5.6 x 10(exp 4) and 3.1 x 10(exp 4) ohm cm(exp 2) respectively while that of pure aluminum was found to be about 1.2 x 10(exp 5) ohm cm(exp 2). In addition, the thickness of the oxide film on the alloys to be less than that of pure aluminum in all solutions examined. Similar results were obtained for chloride containing solutions. These results indicate that there is no correlation between passive current density and the breakdown potential; that is the passive current density and the breakdown potential are two unrelated phenomena. The results of Local Electrochemical Impedance Spectroscopy (LEIS) experiments on a heat treated Al 1.5 at percent Ta alloy, which contained Al3Ta precipitates, revealed that the capacitance of the film over the precipitate is higher than the capacitance of the film over the aluminum portion of this electrode. This indicates that thickness of the film over the precipitate is thinner than the film over aluminum. This interface, between the oxide over the Al3Ta precipitates and the oxide over the aluminum matrix, is perceived as being incoherent and is interpreted here as a 'residual flaw', as described by the crack/heal mechanism proposed by Wood et al.

TERFENOL: A STUDY OF THE PHASE EQUILIBRIUM DIAGRAM AND THE SOLIDIFICATION PROCESS Ph.D. Thesis
M. Anderson Dec. 1993 63 p
(Contract W-7405-eng-82)
(DE94-004883; IS-T-1688) Avail: CASI HC A04/MF A01

Terfenol is a rare earth-iron alloy that was first developed at the Naval Ordnance Laboratory because of its rare magnetostrictive properties. Terfenol is composed of terbium and dysprosium combined with iron in a composition Tb(sub x)Dy(sub 1-x)Fe2, where x is approximately 0.3. The

objective of this work was to determine the growth characteristics of Terfenol and its dependence on solidification rate, temperature gradient, and stoichiometry. Specific goals of this work were to verify the phase equilibria that is currently accepted for the systems DyFe2 and TbFe2, and establish the phase equilibria near the composition Tb(sub 0.3)Dy(sub 0.7)Fe2; establish that Terfenol grows directly from the liquid and that the reaction is occurring under metastable conditions; evaluate whether or not Terfenol can be grown under plane front conditions with a new radiofrequency float zone apparatus; and determine whether or not (111) seeded crystals can be grown and (111) single crystals produced by elimination of dendrites employing growth methods capable of achieving high gradient/solidification rate ratios. MICROSTRUCTURAL DEVELOPMENT AND MECHANICAL BEHAVIOR OF EUTECTIC BISMUTH-TIN AND EUTECTIC INDIUM-TIN IN RESPONSE TO HIGH TEMPERATURE DEFORMATION Ph.D. Thesis
J. L. F. Goldstein Nov. 1993 105 p
(Contract DE-AC03-76SF-00098)
(DE94-005202; LBL-34909) Avail: CASI HC A06/MF A02

The mechanical behavior and microstructure of eutectic Bi-Sn and In-Sn solders were studied in parallel in order to better understand high temperature deformation of these alloys. Bi-Sn solder joints were made with Cu substrates, and In-Sn joints were made with either Cu or Ni substrates. The as-cast microstructure of Bi-Sn is complex regular, with the two eutectic phases interconnected in complicated patterns. The as-cast microstructure of In-Sn depends on the substrate. In-Sn on Cu has a nonuniform microstructure caused by diffusion of Cu into the solder during sample preparation, with regions of the Sn-rich (gamma) phase imbedded in a matrix of the In-rich (beta) phase. The microstructure of In-Sn on Ni is uniform and lamellar and the two phases are strongly coupled. The solders deform nonuniformly, with deformation concentrating in a band along the length of the sample for Bi-Sn and In-Sn on Cu, though the deformation is more diffuse in In-Sn than in Bi-Sn. Deformation of In-Sn on Ni spreads throughout the width of the joint. The different deformation patterns affect the shape of the stress-strain curves. Stress-strain curves for Bi-Sn and In-Sn on Cu exhibit sharp decays in the engineering stress after reaching a peak. Most of this stress decay is removed for In-Sn on Ni. The creep behavior of In-Sn also depends on the substrate, with the creep deformation controlled by the soft P phase of the eutectic for In-Sn on Cu and controlled by the harder (gamma) phase for In-Sn on Ni. When In-Sn on Ni samples are aged, the microstructure coarsens and changes to an array of (gamma) phase regions in a matrix of the (beta) phase, and the creep behavior changes to resemble that of In-Sn on Cu. The creep behavior of Bi-Sn changes with temperature. Two independent mechanisms operate at lower temperatures, but there is still some question as to whether one or both of these, or a third mechanism, operates at higher temperatures. DOE

INFLUENCE OF TUNGSTEN ALLOYING ADDITIONS ON THE MECHANICAL PROPERTIES AND TEXTURE OF TANTALUM
G. T. Gray, III, S. R. Bingert, S. I. Wright, and S. R. Chen 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract W-7405-eng-36)
(DE94-004994; LA-UR-93-4231; CONF-931108-32) Avail: CASI HC A02/MF A01

Tantalum, like all bcc metals exhibits deformation behavior substantially influenced by alloying, temperature, and strain rate. Recently, the mechanical response, in particular the high-strain-rate response, of tantalum and tantalum alloys has received increased interest for ballistic applications. In this paper, recent results on the influence of tungsten alloying additions on the mechanical response and starting crystallographic texture of tantalum-tungsten alloys are presented. The stress-strain behavior of three tantalum alloys containing 2.5, 5, and 10 wt. % W has been investigated as a function of loading path, tension and compression, and strain rate, 10(exp -3) to 8000 s(exp -1). The yield strength and work-hardening rate were found to increase with increasing tungsten alloying content compared to unalloyed Ta. Based on measurements of the surface and centerline textures of the Ta-W alloys, no systematic effect of tungsten content on texture was documented. However, due to variations in mechanical behavior between through-thickness and in-plane properties, a need for complete through-thickness texture measurements is indicated. DOE

NATURE OF DISSOLUTION OF BINARY TANTALUM-TITANIUM ALLOYS BY MOLTEN PLUTONIUM
J. D. Cotton, K. M. Axler, P. C. Lopez, J. H. Steele, and J. I. Archuleta 1994 13 p Presented at the International Symposium on Actinides: Processing and Materials, San Francisco, CA, 27 Feb. - 3 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE94-005090; LA-UR-93-4436; CONF-940215-3) Avail: Issuing Activity (Department of Energy (DOE))

Tantalum hardware has often been used for processing molten Pu where ceramics are inappropriate. However, there has only been limited work on the containment of Pu by Ta alloys. In this regard, we have investigated the interaction of Ta-Ti alloys (20, 40, and 60 wt.% Ti) with molten Pu at 850 and 1000 C. Microstructures of Pu/alloy interfaces were characterized chemically and metallographically following various exposures to liquid Pu. Dissolution does not proceed uniformly, but appears to initiate by intergranular attack to a shallow depth and then progress by the formation of a stable mushy zone at the liquid/solid interface. Resistance to dissolution by molten Pu increases with Ta content. DOE

A COMPARISON OF THE EVOLUTION OF COLD AND HOT DEFORMATION MICROSTRUCTURES AND TEXTURES IN FCC METALS
D. A. Hughes and N. Hansen 1993 18 p Presented at the TMS Symposium on Advances in Hot Deformation Textures and Microstructures, Pittsburgh, PA, 22 Oct. 1993
(Contract DE-AC04-76DR-00789)
(DE94-005103; SAND-94-8487C; CONF-9310260-1) Avail: CASI HC A03/MF A01

Microstructures and textures which develop during cold deformation are compared to those which develop during hot deformation. This comparison is made using the evolutionary framework of grain subdivision and the formation of low energy dislocation structures. During deformation grains are subdivided into differently deforming regions separated by geometrically necessary dislocation boundaries. These boundaries include dense dislocation walls, microbands, lamellar boundaries, and subgrains. Grain subdivision occurs as a result of the requirement for strain accommodation balanced by energy considerations. This grain subdivision weakens the texture and increases the texture scatter. The tendency for grain subdivision decreases with increasing temperature of deformation with implications for the microstructural evolution and the texture formation. DOE

STUDY OF NUCLEATION AND GROWTH IN Al-Zn ALLOYS USING TEM
G. Sundar (Washington State Univ., Pullman.), J. J. Hoyt (Washington State Univ., Pullman.), E. A. Kenik, and S. Spooner 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE94-006312; CONF-931108-75) Avail: CASI HC A02/MF A01

Nucleation and growth studies were conducted on Al-Zn alloys at several temperatures using transmission electron microscopy (TEM) with an in-situ furnace. The value of the critical undercooling was established by noting the lowest temperature at which precipitates were no longer observed, following a quench into the two-phase metastable region. These results were compared with the Langer-Schwartz model of nucleation and growth in which it is predicted that the half-completion time (i.e, the time required for the supersaturation to reach half its initial value) diverges for initial supersaturations which are higher than those predicted by the classical nucleation theory. The utility of the arbitrary Lagrangian-Eulerian (ALE) code format is evaluated in the context of use in simulating metal forming processes. Emphasis is on large deformation processes such as casting, forging and extrusion. The basic point at issue is whether the continual remapping capability inherent in the ALE approach can provide advantages relative to the more standard approach of using a Lagrangian mesh but allowing for isolated remeshing as required. A particular ALE implementation, ALE3D, is used as the basis for the discussion. Pros and cons for this approach are presented along with illustrations of its application to actual forming problems. PULL-TEST ADHESION MEASUREMENTS OF DIAMONDLIKE CARBON FILMS ON SILICON CARBIDE, SILICON NITRIDE, ALUMINUM OXIDE, AND ZIRCONIUM OXIDE
R. A. Erck, F. A. Nichols, and J. F. Dierks Oct. 1993 20 p Presented at the 40th National Symposium of the American Vacuum Society, Orlando, FL, 15-19 Nov. 1993
(Contract W-31-109-eng-38)
(DE94-005469; ANL/ET/CP-81579; CONF-9311104-17) Avail: CASI HC A03/MF A01

Hydrogenated amorphous carbon films or diamondlike carbon (DLC) films were formed by ion-beam deposition of 400 eV methane (CH4) ions on several smooth and rough ceramics, as well as on ceramics coated with a layer of Si and Ti. Adhesion was measured by the pin-pull method. Excellent adhesion was measured for smooth SiC and Si3N4, but the adhesion of DLC to Al2O3 and ZrO2 was negligible. The use of a Si bonding interlayer produced good adhesion to all the substrates, but a Ti layer was ineffective because bonding between the DLC film and Ti was poor. The presence of surface roughness appeared to greatly increase the measured adhesion in all cases. Bulk thermodynamic calculations are not directly applicable to bonding at the interface. If the standard enthalpy of formation for reaction between CH4 and substrate is calculated assumpting a carbide or carbon phase is produced, a relation is seen between reaction enthalpy and relative adhesion. Large positive enthalpies are associated with poor adhesion; negative or small positive enthalpies are associated

with good adhesion. This relation between enthalpy and adhesion was also observed for DLC deposited on Si. Lack of adhesion to Ti was attributed to inadvertent formation of a surface oxide layer that rendered the enthalpy for reaction with CH4 strongly positive and similar in magnitude to that for Al2O3 and ZrO2. ADHESION OF ELECTROLESSLY DEPOSITED Ni(P) ON ALUMINA CERAMIC Ph.D. Thesis
Jan Willem Severin 1993 216 p Prepared in cooperation with Philips Gloielampenfabrieken N.V., Eindhoven, Netherlands
(ETN-94-95358) Avail: CASI HC A10/MF A03

The adhesion of electroless Ni(P) to alumina is addressed. Attention is paid to the procedures and techniques used to study the adhesion, the adhesion strengths obtained and the models proposed to explain the adhesion. The formation of the interface between Ni(P) and alumina is studied. The changes in structure and chemical composition of the substrate surface is analyzed after each successive process step. The adhesion is measured with peel tests and direct pull off tests. Quantitative aspects of both adhesion measurement procedures are highlighted. A fracture mechanics approach is followed for the interpretation of the adhesion measurement results. The metal-ceramic interface and the fracture surfaces are analyzed both on micrometer and on nanometer scale in order to find a relation between the measured adhesion and interface chemistry. The influence of thermal treatments upon the adhesion strength is investigated. Special attention is paid to a distinction between changes in bulk mechanical properties in the metal film and intrinsic adhesion. The influence of substrate surface chemistry upon the adhesion is investigated. Thin metal oxide layers are deposited on the ceramic surfaces. These metal oxide surfaces are metallized and the adhesion and interface chemistry are characterized. Differences in adhesion are tentatively explained in terms of surface chemistry and microroughness. A completely different procedure is followed to apply the Pd catalyst, required to start the electroless deposition process. Pd layers are evaporated instead of the usual wet chemical procedure. A thin titanium layer is applied for improving the adhesion of the Pd nucleation layer on the substrate. The adhesion and the fracture path are determined and a detailed analysis is made of the bonding at the metal-ceramic interface within the first metal monolayers. ESA

ELECTRODEPOSITION OF BISMUTH ALLOYS BY THE CONTROLLED POTENTIAL METHOD Ph.D. Thesis
Lopez F. J. Alvarez 1993 129 p
(DE94-605318; INIS-mf-13725) Avail: CASI HC A07/MF A02 (US Sales Only)

We worked with the electrodeposition of three bismuth alloys, the composition of the first electrolyte was: 0.3 g/l Bi; 20 g/l Ni; and the conditions were pH = 5.2 - 5.6; T = 25 Centigrade degrees; current density 0.3 A / dm(sup 2) - 6.6 A / dm(sup 2). Following alloy was between Bi - Pb, composition of the electrolyte was 3.18 g/l Bi (metallic); 31.81 g/l Pb (Pb(NO3)2) pH : 1; T = 20 Centigrade degrees; current density 10.20 A/dm(sup 2) . The third electrolyte was Bi-Cu, its composition was: 20.89 g/l Bi; (metallic) 63.54 g/l Cu (Cu(NO3)2) pH : 1.5 - 1.8; T = 25-30 Centigrade degrees; current density 1-2 A/dm(sup 2) . The best results were obtained with the third electrolyte. The purpose of this work was to experiment with different parameters like temperature, pH and the electrolyte concentration to obtain a bismuth alloy. DOE

HIGH DAMAGE THRESHOLD ANTI-REFLECTORS BY PHYSICAL VAPOR DEPOSITED AMORPHOUS FLUOROPOLYMER
R. Chow, M. K. Spragge, G. E. Loomis, I. M. Thomas, F. Rainer, R. L. Ward, and M. R. Kozlowski Nov. 1993 13 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-004865; UCRL-JC-114841; CONF-931054-2) Avail: CASI HC A03/MF A01

High laser-resistant anti-reflective coatings were made from an amorphous fluoropolymer (Teflon AF2400) material by physical vapor deposition. Single layers of Teflon AF2400 were thermally deposited in a vacuum chamber. Refractive index and adhesion of the coatings were determined as a function of deposition rate (2 to 20 (Angstrom)/s), substrate temperature (20 to 200C), and glow-discharge bias potential (-1500 to 1500 V). An anti-reflective coating of an amorphous fluoropolymer (Teflon AF2400) had a laser resistance of greater than 47 J/cm(exp 2) (1.06 (mu)m, 3-ns pulselength) and is transparent from 200 nm to 1600 nm. The majority of the coatings had a 1.30 refractive index, similar to that of the bulk material. Scanning electron microscopy and preliminary nuclear magnetic resonance observations indicated that morphological changes caused the variations in the refractive index rather than compositional changes. The coatings adhered to fused silica and silicon wafers under normal laboratory handling conditions. Scotch tape with 12.6 gr/mm tension was sufficient to pull off every coating from fused silica substrates. DOE

ALUMINA CERAMIC: A COST EFFECTIVE REPLACEMENT FOR TITANIUM IN DEEP SUBMERGENCE PRESSURE HOUSINGS Final Report
Jerry D. Stachiw Sep. 1993 18 p
(AD-A275640; NCCOSC/RDT/E-TD-2582) Avail: CASI HC A03/MF A01

Alumina ceramic's high compressive strength and modulus of elasticity, coupled with its low density, make it feasible to routinely fabricate cylindrical pressure housings with 0.5 weight/displacement ratios for 20,000 ft (6100 m) service. This compares favorably to optimally designed titanium cylindrical housings with 0.86 weight/displacement ratio. This presentation, by J.D. Stachiw, describes past experiences with glass and ceramic pressure housings and presents NCCOSC ceramic housing program objectives, approach, findings, and applications. DTIC

ANALYSIS OF COST: CVD DIAMOND DEPOSITION AND FINISHING Quarterly Report No. 2
1993 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-C-2044)
(AD-A275586) Avail: CASI HC A03

This report describes several methods for polishing CVD diamond films, which can be applied separately or in conjunction with each other. From industry interviews, IBIS determined that the required surface roughness for the subsequent metallization operation is on the order of 0.1 microns, and polishing operations must be chosen to meet this specification while maximizing material removal rates. According to the experts surveyed, conventional abrasive lapping still remains the prevalent technology for polishing CVD diamond films, although Hot Iron Polishing, Reactive Plasma, and Ion Milling approaches have been considered. The IBIS Technical Cost Model, therefore, assumes only abrasive lapping as the finishing operation, but allows exploration into other technologies. In general, the polishing rate attained with each technology depends greatly on the quality of the deposited diamond films, as measured by the original flatness and surface roughness. The chemical state of the diamond films, with respect to amorphous carbon content and doping levels, can also influence the polishing rate significantly. DTIC

SUPERPLASTICITY IN FINE-GRAINED CERAMICS Final Report, 1 Jul. - 31 Dec. 1993
T. G. Nieh 31 Jan. 1994 42 p

(Contract MIPR-ARO-131-93)
(AD-A275461; UCRL-CR-116116; ARO-31207.1-MS) Avail: CASI HC A03/MF A01

The superplastic deformation behavior of fine-grained, 20% alumina/yttria-stabilized tetragonal zirconia (20%Al2O3NTZP) under conditions of biaxial gas-pressure deformation is described. Sheet specimens were deformed into hemispherical caps at temperatures ranging from 1450 C - 1600 C and at imposed gas pressures of 345 and 690 KPa. For the conditions examined, hemispherical caps were formed at times ranging from 1000 s to 2.1 x 104 s. The correlation between data obtained in uniaxial tensile testing and the behavior observed during the biaxial deformation experiments is discussed. The high-temperature deformation behavior of a SiC whisker-reinforced, yttria-stabilized, tetragonal zirconia polycrystalline composite containing 20 vol % SiC whiskers (SiC/Y-TZP) has also been investigated. Tensile tests were performed in vacuum at temperatures from 1450 C to 1650 C and at strain rates from 10(exp -3) to 10(exp -5) s(exp -1). The material exhibits useful high temperature engineering properties (e.g., approx. 100 MPa and 16% elongation at T = 1550 C and at a strain rate of 10(exp -4) s(exp -1)). The stress exponent was determined to be n=2. Scanning electron microscopy was used to characterize the grain size and morphology of the composites, both before and after deformation. Both dynamic and static grain growth were observed during deformation. The morphology of ceramic reinforcements appears to affect strongly the plastic deformation properties of Y-TZP. A comparison is made between the properties of monolithic Y-TZP, 20 wt.% Al2O3 particulate-reinforced Y-TZP (Al2O3/Y-TZP), and SiCN-TZP composites. Superplasticity deformation processing of ceramics has also been performed. DTIC

POLYMER INFILTRATION STUDIES Progress Report, 1 Jun. 1993 - 31 Mar. 1994
Joseph M. Marchello Apr. 1994 9 p
(Grant NAG1-1067)
(NASA-CR-195729; NAS 1.26:195729) Avail: CASI HC A02/MF A01

During the past three months, significant progress has been made on the preparation of carbon fiber composites using advanced polymer resins. The results are set forth in recent reports and publications, and will be presented at forthcoming national and international meetings. Current and ongoing research activities reported herein include: textile composites from powder-coated towpreg - role of surface coating in braiding; prepregger hot sled operation in making tape from powder coated tow; ribbonizing powder-impregnated towpreg; textile composites from powder-coated towpreg - role of bulk factor in consolidation; powder curtain prepreg process improvements in doctoring of powder; and hot/cold shoe for ATP open-section part warpage control. CORROSION INHIBITION BY ELECTRODEPOSITED CONDUCTIVE-POLYMER FILM Final Report, 15 Aug. 1989 - 30 Jun. 1993
Dale P. Barkey 30 Oct. 1993 9 p
(Contract DAAL03-89-K-0138)
(AD-A275456; ARO-26449.4-MS) Avail: CASI HC A02/MF A01

Conductive polymer coatings were deposited on steel and titanium substrates by electrooxidative polymerization of poly(3-methylthiophene). The properties of the polymer coatings in acidic, basic and chloride containing solutions were evaluated by electroanalytical means, and the effectiveness of the coatings in providing anodic protection of the substrate were evaluated. The polymer contains a reversible couple with an equilibrium potential near 0.4V positive of Ag/AgCl sat'd KCl. It is effective in passivating 430 stainless steel and titanium in sulfuric acid solution at temperatures below 50 C. Excursions of potential negative of -0.3V result in irreversible reduction of the polymer to a nonconductive state. The polymer is also rendered permanently inactive by basic solutions and by chloride. DTIC

This final report covers all of the efforts and results during the awarded contract period. The format is generally a chronological account of events; however, several projects were performed concurrently. These simultaneous projects are discussed separately rather than chronologically to avoid confusion. An account of the first experiments and results are addressed. The efforts and results from an extensive fused silica grinding and polishing study is given. The bulk of the research performed during the contract period was devoted to the fabrication of optical quality fused silica flats. The results of the optical fabrication of other materials, such as potassium deuterium phosphate (KD*P) and crystalline quartz, are discussed. A list of publications and conference presentations associated with this effort is provided. Derived from text

SURFACE ENERGY CHANGES PRODUCED BY ULTRAVIOLET-OZONE IRRADIATION OF POLY(METHYLMETHACRYLATE), POLYCARBONE AND POLYTETRAFLUOROETHYLENE
A. B. Ponter (University of Southwestern Louisiana, Lafayette.), W. R. Jones, Jr., and R. H. Jansen Jan. 1994 11 p
(RTOP 505-63-5A)
(NASA-TM-106460; E-7806-1; NAS 1.15:106460) Avail: CASI HC A03/MF A01

Contact angles of water and methylene iodide were measured as a function of UV/O3 treatment time for three polymers: poly(methylmethacrylate) (PMMA), polycarbonate, and polytetrafluoroethylene (PTFE). Surface roughnesses were also measured. Surface free energies were then calculated using relationships developed by Kaelble and Neumann. The surface energy of polycarbonate was found to increase (60 percent) during UV/O3 treatment. However, calculations on PMMA were hampered by the formation of a water soluble surface product. On PTFE surfaces, the UV/O3 treatment etched the surface causing large increases in surface roughness, rendering contact angle measurements impossible. It is concluded that care must be taken in interpreting contact angle measurements and surface energy calculations on UV/O3 treated polymer surfaces. Author (revised)

As a result of the phase 1 research, we can reproduce clad silicon carbide films onto graphite rod substrates. During the course of our research, we varied the melt composition, temperature and crucible material. The resultant silicon carbide films were confirmed, independently by Charles Evans Associates using electron microscopy and elemental x-ray analysis. The minimum temperature for silicon carbide formation was determined. The relationship between film thickness and maximum melt temperature was studied. The importance of complete oxygen exclusion was determined. The presence of the proprietary flux was found to be essential in this regard. The thickness and integrity of these films are not yet suitable for commercial applications. It is anticipated that the use of higher temperatures will yield silicon carbide films suitable for extreme environment applications. A new high-efficiency high-temperature furnace was designed with a maximum working temperature of 2000 C. DTIC

THERMAL EXPANSION AND ELASTIC ANISOTROPY IN SINGLE CRYSTAL Al2O3 AND SiC REINFORCEMENTS
Jonathan A. Salem, Zhuang Li, and Richard C. Bradt Mar. 1994 12 p Presented at the ASME Symposium on Advances in Composite Materials and Structures, Anaheim, CA, 10-12 Dec. 1986; sponsored by ASME
(NASA-TM-106516; E-8635; NAS 1.15:106516) Avail: CASI HC A03/MF A01

In single crystal form, SiC and Al2O3 are attractive reinforcing components for high temperature composites. In this study, the axial coefficients of thermal expansion and single crystal elastic constants of SiC and Al2O3 were used to determine their coefficients of thermal expansion and Young's moduli as a function of crystallographic orientation and temperature. SiC and Al2O3 exhibit a strong variation of Young's modulus with orientation; however, their moduli and anisotropies are weak functions of temperature below 1000 C. The coefficients of thermal expansion exhibit significant temperature dependence, and that of the non-cubic Al2O3 is also a function of crystallographic orientation. Author (revised)

EFFECT OF SURFACE CONDITION ON STRENGTH AND FATIGUE BEHAVIOR OF ALUMINA CERAMIC Final Report
Nov. 1993 90 p
(AD-A275053; NCCOSC/RDT/E-TD-2584) Avail: CASI HC A05/MF A01

The United States Navy is developing deep-water submersible vessels and, in an effort to attain the appropriate strength and buoyancy characteristics, is investigating the suitability of ceramics. The vessels typically consist of cylindrical sections and hemispherical end caps of a ceramic such as aluminum oxide (alumina), which are joined together via metallic rings made of a titanium alloy. Tests of such vessels have shown that fatigue cracks may arise in the alumina during submergence-emergence cycles, which ultimately lead to failure of the vessel. This document presents results from a one-year program designed to develop a fatigue-crack-growth resistant interface between the alumina cylinder sections and the titanium alloy rings. DTIC

Organometallic complexes formed by metallocene/methylalumoxane belong to the most active catalysts for olefin polymerization known today. A general definition of metallocene catalyst used in ethylene co- and terpolymerizations with dienes is given. Cyclopentadienylide catalyst systems using a metallocene complex in conjugation with an alumoxane catalyst or reaction product thereof are suitable for preparing ethylene diene copolymers. The metallocene catalyst may be represented by the general formula (Cp)(sub m)MRnR'(sub n) wherein Cp is a substituted cyclopentadienyl ring; M is a group IVB, VB or VIB transition metal; R and R' are independently selected halogen, hydrocarbyl group, or hydrocarboxyl groups having 1-20 carbon atoms; m = 1-3, n = 0-3, p = 0-3, and the sum of m+n+p equals the oxidation state of M. (AD-A275396; ARO-28884.5-MS) Avail: CASI HC A03

Both solid to gas (CaSO4 + SiO yields SiO3 + SO2 and Si3N4 + 3C (diamond) and 3SiC + 2 N2) can be shock-induced at ballistic velocities. Because of the endothermic nature of the gas-producing reactions, the extent of reactions observed are limited to interfaces. We found the above reactions proceed to a lesser extent than calculation by equilibrium thermodynamic calculations. Reaction products are found to be 0.01 times those calculated for equilibrium. We show that the extent of reaction, rather than limited by the usual diffusion processes, appears to be controlled by dynamic mixing processes arising from Rayleigh-Taylor instabilities at, for example, CaSiO4-SiO2 interfaces. We apply a theory developed by Drucker to account for the observed extent of reaction. DTIC

LOW DIELECTRIC POLYIMIDE FIBERS Patent Application
William E. Dorogy, Jr., inventor (to NASA) (Lockheed Corp., Hampton, VA.) and Anne K. St.Clair, inventor (to NASA) 10 Apr. 1992 21 p
(NASA-Case-LAR-14526-1; NAS 1.71:LAR-14526-1;
US-Patent-Appl-SN-870003) Avail: CASI HC A03/MF A01

A high temperature resistant polyimide fiber that has a dielectric constant of less than 3 is presented. The fiber was prepared by first reacting 2,2-bis (4-(4aminophenoxy)phenyl) hexafluoropropane with 2,2-bis (3,4-dicarboxyphenyl) hexafluoropropane dianhydride in an aprotic solvent to form a polyamic acid resin solution. The polyamic acid resin solution is then extruded into a coagulation medium to form polyamic acid fibers. The fibers are thermally cured to their polyimide form. Alternatively, 2,2-bis (4-(4-aminophenoxy)phenyl) hexafluoropropane is reacted with 2,2-bis(3,4-dicarboxyphenyl) hexafluoropropane dianhydride to form a polyamic acid, and the polyamic acid is chemically converted to its polyimide form. The polyimide is then dissolved in a solvent to form a polyimide resin solution, and the polyimide resin is extruded into a coagulation medium to form a polyimide wet gel filament. In order to obtain polyimide fibers of increased tensile properties, the polyimide wet gel filaments are stretched at elevated temperatures. The tensile properties of the fibers were measured and found to be in the range of standard textile fibers. Polyimide fibers obtained by either method will have a dielectric constant similar to that of the corresponding polymer, viz., less than 3 at 10 GHz. NASA

LUBRICATION OF SPACE SYSTEMS
Robert L. Fusaro Mar. 1994 28 p Proposed for presentation at the Society of Tribologists and Lubrication Engineers Annual Meeting, Pittsburgh, PA, 2-5 May 1994; sponsored by the Society of Tribologists and Lubrication Engineers
(RTOP 506-43-41)
(NASA-TM-106392; E-8217; NAS 1.15:106392) Avail: CASI HC A03/MF A01

NASA has many high-technology programs plannned for the future, such as the space station, Mission to Planet Earth (a series of Earth-observing satellites), space telescopes, and planetary orbiters. These missions will involve advanced mechanical moving components, space mechanisms that will need wear protection and lubrication. The tribology practices used in space today are primarily based on a technology that is more than 20 years old. The question is the following: Is this technology base good enough to meet the needs of these future long-duration NASA missions? This paper examines NASA's future space missions, how

mechanisms are currently lubricated, some of the mechanism and tribology challenges that may be encountered in future missions, and some potential solutions to these future challenges. Author

EXPERIMENTAL DETERMINATION OF ORTHOTROPIC ELASTIC CONSTANTS
Anders Henriksson Sep. 1993 18 p Sponsored by Foersvarets Materialverk, Stockholm, Sweden
(FFA-TN-1991-35; ETN-94-95525) Avail: CASI HC A03/MF A01

Conventional methods for determining the elastic constants were investigated in order to find a simple method to provide the full stiffness matrix of an orthotropic material. Since the conventional methods were found not to meet these requirements, another method was tried based on the compression of cubic specimens and measurement of the strains using an extensometer designed for this purpose. The elastic parameters E(sub 1), E(sub 2), E(sub 3), G(sub 12), nu(sub 12), nu(sub 23), and nu(sub 31) were measured using this method on only two kinds of specimens. The accuracy was not satisfactory when properties associated with the 1-direction were measured due to the small displacements involved. The properties in the thickness direction were, however, determined successfully. There is a potential to improve the accuracy of the method and achieve better accuracy even for parameters associated with the 1-direction. ESA

IRRADIATION POLYMERIZATION OF BISMALEIMIDE RESINS [POLYMERISATION DES RESINES BISMALEIMIDES SOUS IRRADIATION]
Daniel Beziers, Vincent Denizot, and Marie-Florence Grenier-Loustalot 1993 15 p In FRENCH Presented at Journee Polyimides Structuraux, Arcueil, France, 12 Jan. 1993
(Rept-932-430-105; ETN-94-95463) Avail: CASI HC A03/MF A01

Within research on the polymerization of bismaleimide resins under irradiation, the mechanisms and kinetics of bismaleimide resin polymerization was studied on model systems and industrial prepolymers, taking into account the influence of several parameters such as the concentration of the active diluent, and the nature and strength of the dose (electrons or X-rays). A methodology based on physiochemical studies by infrared absorption spectroscopy and solid C-13 NMR (Nuclear Magnetic Resonance) CP MAS was developed to quantify the chemical species created or residual in the lattice. The results obtained (reaction progress, structure of formed lattice) are correlated with thermal resistant and compared with those obtained by thermal polymerization. ESA

VACUUM VAPOR DEPOSITION Patent Application
Richard M. Poorman, inventor (to NASA) and Jack L. Weeks, inventor (to NASA) 3 Feb. 1994 13 p
(NASA-Case-MFS-28652-1; NAS 1.71:MFS-28652-1;
US-Patent-Appl-SN-191309) Avail: CASI HC A03/MF A01

A method and apparatus is described for vapor deposition of a thin metallic film utilizing an ionized gas arc directed onto a source material spaced from a substrate to be coated in a substantial vacuum while providing a pressure differential between the source and the substrate so that, as a portion of the source is vaporized, the vapors are carried to the substrate. The apparatus includes a modified tungsten arc welding torch having a hollow electrode through which a gas, preferably inert, flows and an arc is struck between the electrode and the source. The torch, source, and substrate are confined within a chamber within which a vacuum is drawn. When the arc is struck, a portion of the source is vaporized and the vapors flow rapidly toward the substrate. A reflecting shield is positioned about the torch above the electrode and the source to ensure that the arc is struck between the electrode and the source at startup. The electrode and the source may be confined within a vapor guide housing having a duct opening toward the substrate for directing the vapors onto the substrate. NASA

POLY(ARYLENE ETHER-CO-IMIDAZOLE)S AS TOUGHNESS MODIFIERS FOR EPOXY RESINS Patent Application
Patricia D. McDaniel, inventor (to NASA) (College of William and Mary, Williamsburg, VA.) and John W. Connell, inventor (to NASA) 18 Jan. 1994 21 p
(NASA-Case-LAR-15229-1-CU; NAS 1.71:LAR-15229-1-CU;
US-Patent-Appl-SN-186054) Avail: CASI HC A03/MF A01

A toughened epoxy was prepared by reacting an epoxy resin with a poly(arylene ether-co-imidazole)s (PAEI). The epoxy resin comprises N,N,N',N'tetraglycidyl-4,4'- methylenebisbenzenamine and 4-aminophenyl sulfone. The PAEI was prepared by reacting an aromatic bisphenol, a bisphenol imidazole, and an activated aromatic dihalide or dinitro compound in the presence of potassium carbonate in a polar aprotic solvent at an elevated temperature. The epoxies which were modified with these particular PAEI's showed a significant increase in toughness with only a 10 weight percent loading of the PAEI into the epoxy. These toughened epoxies were used to prepare composites and molded parts. NASA

RULES AND DEFINITION OF THE RANGE OF PAINTS APPLIED ON AERONAUTICAL STRUCTRURAL COMPOSITES [REGLES ET DEFINITION DES GAMMES DE PEINTURES APPLIQUEES SUR LES COMPOSITES AERONAUTIQUES STRUCTURAUX]
P. Michelin and P. Dublineau 1993 13 p In FRENCH
(Rept-932-600-106; ETN-94-95485) Avail: CASI HC A03/MF A01

The advantages of composite materials which have led to their increased use in aeronautical structures are listed. Their major inconveniences--specifically those that must be protected by layers of paint--are addressed. The different types of composites used, the requirements they necessitate in paints, the application of these paints, the treatment of the surfaces before application of the paints, the measurement of the interphase paint/composite cohesion, the fracturing of the protective film, and the choice of paints are addressed. It is concluded that in order to assure perfect adhesion between paint and composite, certain basic rules should be followed: verification of the absorptivity of the surface; a minimal thickness of paint compatible with the esthetic demands; good knowledge of the materials and their surface; and good communication between supplier and client. Novel polyimides containing pendent siloxane groups (PISOX) were prepared by the reaction of functionalized siloxane compounds with hydroxy containing polyimides (PIOH). The pendent siloxane groups on the polyimide backbone offer distinct advantages such as lowering the dielectric constant and moisture resistance and enhanced atomic oxygen resistance. The siloxane containing polyimides are potentially useful as protective silicon oxide coatings and are useful for a variety of applications where atomic oxygen resistance is needed.

A PHOTOEMISSION ELECTRON MICROSCOPE INVESTIGATION OF CHEMICAL VAPOR DEPOSITION DIAMOND FILMS AND DIAMOND NUCLEATION Ph.D. Thesis
Congjun Wang 1993 175 p
Avail: Univ. Microfilms Order No. DA9322371

CVD diamond nucleation is investigated using the hot filament technique. The stability of CVD diamond at elevated temperatures in vacuum, O2, and atomic hydrogen environments are studied using photoemission electron microscopy (PEEM) combined with in-vacuo x ray photoelectron spectroscopy (XPS). Dissolution, oxidation, and atomic hydrogen etching processes of CVD diamond are observed in real-time. Low field cold electron emission from CVD diamond films has been observed for the first time by PEEM.

Nucleation density Mo substrates could be increased from 10(exp 4) to 10(exp 8)/cm(exp 2) by polishing. Heating the substrate to 870 C in vacuum prior to deposition, or above 1000 C at the beginning of deposition, reduced nucleation by more than 100-fold. Reduction in nucleation sites is attributed to annealing. Nucleation on Mo2C substrates was found to be very poor (10(exp 4)/cm(exp 2)), which shows carbide alone does not promote nucleation. Carbide formation may remove nucleation sites. CVD diamond was found to dissolve into the Mo substrate in vacuum at about 1200 C. XPS showed formation of Mo2C when the diamond dissolved. Diamond oxidation to gas phase products occurred directly at about 600 C, with no observable participation by the substrate. No detectable etching by atomic hydrogen at a pressure of 1 x 10(exp -4) torr was observed. Boron doped and 'pure' CVD diamond films were found to emit electrons at room temperature under the action of the accelerating electric field of the PEEM (about 30 kV/cm) without photon excitation. The mechanism underlying this phenomenon was investigated with PEEM and by studying the emission current versus voltage characteristics of the CVD diamond films. Morphology and crystalline orientation were found to play only a minor role. Impurities in the CVD diamond structure lowers the potential barrier substantially; tunneling of electrons into the vacuum is facile. The effective work function of the emitting CVD diamond films is measured to be about 0.1 eV. Dissert. Abstr.

ANALYSIS OF PRESSURELESS DENSIFICATION OF CERAMIC MATRIX COMPOSITES Ph.D. Thesis
Wei Hong 1993 79 p
Avail: Univ. Microfilms Order No. DA9326595

A finite element method implementing viscoelastic formulations is developed and utilized for analyzing the densification behavior of ceramic matrix composites during a pressureless sintering process. The effort is focused on the investigation of the drastic reduction in densification rates of polycrystalline ceramics reinforced with a second phase of inert, rigid particles or whiskers, compared to that of single phase ceramics. The second phase is relatively rigid inclusions and generally considered to provide a constraint to the sintering matrix. The ceramic matrix is presumed to be viscoelastic. The sintering potential used in the analysis is derived from sintering experiments on the unconstrained matrix, noting that the free strain rate for the constrained matrix is generally different from that of the unconstrained identical matrix. The finite element analysis is performed with several physical and geometric models. The effect of inclusion shape on the densification rates is investigated through a set of geometric models containing a single spherical, a single ellipsoidal and a single cylindrical inclusion, respectively. The densification rates of the sintering matrix are found to be affected significantly by the inclusion shape. The single cylindrical inclusion model serves as an upper bound while the spherical inclusion provides a lower bound for the constraint in these single inclusion models. The single cylindrical inclusion model is also used to study the effects of various constitutive relations. Sintering potential is assumed to depend on the length of sintering time, matrix density and grain size. The interaction among inclusions is investigated using a two dimensional multiple inclusion model. The effect of homogeneous and heterogeneous distribution of initial density is also investigated by accounting for the competition between sintering and pore coarsening. Dissert. Abstr.

STUDY OF NONLINEAR OPTICAL POLYMERS AND THEIR APPLICATIONS IN OPTICAL WAVEGUIDES Ph.D. Thesis
Yong Ming Chen 1992 143 p
Avail: Univ. Microfilms Order No. DA9305325

This thesis describes the investigations on second-order novel nonlinear optical (NLO) polymeric materials and their applications. The first chapter introduces the subject matter of the dissertation. The second chapter describes parallel plate poling and corona discharge poling to achieve second-order NLO properties. The corona discharge poling provides certain advantages such as higher effective poling field which aligns NLO molecules more efficiently. An existing theoretical model has been used to understand corona poling and to calculate the effective poling field. In the third chapter, the second harmonic generation (SHG) method is discussed and developed to characterize NLO polymeric films. Using SHG measurements, second-order NLO coefficients of polymeric films are determined. Most NLO polymeric films have absorption in the doubled frequency region for a Nd:YAG laser (1.064 micron). The values of second-order NLO coefficients are resonantly enhanced. The derivation of absorption correction of second-order NLO coefficients has been carried out. The absorption corrected d(sub 33) value for poled and crosslinked DGEBA-DO3C film is 31 pm/V. The fourth chapter deals with the stabilization of second-order nonlinearity of polymeric materials. The side chain, photocrosslinked, sol-gel, thermosetting and polyimide systems have been developed to investigate and improve the stability of poled polymeric films. The fifth chapter describes the characterization of linear and quadratic electro-optic (EO) effects of polymers. The linear EO coefficients of poled polymeric films have been characterized by the reflection measurement technique. Using a modified Michelson interferometer, the quadratic EO coefficients have been determined. The sixth chapter reports the investigation of optical waveguides and the waveguide applications. A series of experiments, such as prism coupling and optical loss measurement, have been performed to determine linear properties of waveguides (propagation constant, refractive indices, film thickness, and optical loss). Using these parameters, planar and channel waveguides have been designed and fabricated. Also the SHG in these waveguides have been carried out. The SHG conversion efficiency of a polymeric channel waveguide was 0.1 percent/W. Bright green light was observed even using the Nd:YAG laser in cw mode. Dissert. Abstr.

INORGANIC POLYMER-DERIVED CERAMIC MEMBRANES
C. J. Brinker, R. Sehgal, N. Raman, P. R. Schunk, and T. J. Headley 1993 15 p Presented at the Fuels Technology Contractors' Review Meeting, Morgantown, WV, 16-18 Nov. 1993
(Contract DE-AC04-76DP-00789)
(DE94-000082; CONF-931156-25) Avail: CASI HC A03/MF A01

Polymeric silica sols were used to prepare membranes on commercial (gamma)-Al2O3 supports. Aging of the silica sols was shown to be effective to form discrete membrane layers. He/N2 selectivity factors exceeding ideal Knudsen values were observed when the sols were prepared under conditions in which the condensation rate was minimized. It is proposed that the average pore size of the membrane depends on the balance of capillary pressure and modulus during membrane deposition and that the breadth of the pore size distribution might be influenced by the extent of condensation accompanying membrane deposition. The use of organic templates may allow independent control of pore size, pore shape, and pore volume. The membranes are to be used in processing natural gas (gas separation/purification). DOE

TRANSIENT THERMAL FATIGUE OF CERAMIC COMPOSITES Ph.D. Thesis
Arvind K. Sinha 1992 294 p
Avail: Univ. Microfilms Order No. DA9314079

Ceramic composite materials were developed for use at high temperatures and are subjected to cyclic thermal loads. These loads are an important factor in determining the reliability and mechanical load carrying capability of the composite. Specifically, the effect of cyclic thermal loads is to cause thermal stresses at the interface between the fiber and the matrix and cause debonding between these components. In turn, such debonding results in a change in the mechanical and thermal properties of the composite. Consequently, it is important to understand the mechanics of fiber-matrix interaction under thermal loads in order to optimize the behavior of composites at high temperatures. The changes in stiffness for a Nicalon/CAS-2 unidirectional composite resulting from cyclic heating and cooling were investigated. The experimental measurements were made using an ultrasonic through-transmission method. It is shown that slower cooling rates result in degradation of stiffness mainly in the C22 and C33 direction through interface debonding. For a higher cooling rate, a decrease in C11 is observed due to surface matrix cracks. The behavior of Nicalon/CAS-2 composite under transient thermal load is studied using the various thermomicromechanical models. These models are then used to calculate thermomechanical stresses produced thermal load application. Using three-phase thermomechanical models, it is shown that the behavior of the matrix and the fiber-matrix interface is dependent on the transversely isotropic material surrounding the matrix. The finite element modeling done on the Nicalon/CAS-2 composite verified the results obtained during thermal cycling experiments. To calculate the stiffness degradation, the concept of equivalent homogeneity was applied. The behavior of an interface and a

matrix crack subjected to transient heating and cooling were studied using the single cell fiber-matrix model. Based on this model, the nondimensional strain energy release rate was calculated. Results show that when the critical strain energy release rate for the interface is similar or lower than that of the matrix, the interface crack will propagate before the matrix crack. Dissert. Abstr.

THE EFFECT OF TEMPERATURE ON CREEP AND PHYSICAL AGEING OF PVC

P. E. Tomlins, B. E. Read, and G. D. Dean Mar. 1993 28 p Sponsored by Dept. of Trade and Industry, United Kingdom

(ISSN 0959-2423)

(NPL-DMM(A)-93; ETN-94-95504) Copyright Avail: Issuing Activity (National Physical Laboratory, Teddington, Middlesex TW11 0LW, United Kingdom)

Tensile creep data was obtained for PVC at a number of temperatures ranging from 21.5 to 58 C. The results were obtained from specimens of different age characterized by the elapsed time t(sub e) between quenching a sample from 85 C to the test temperature and the start of the creep test. A model for interpreting nonlinear creep data was developed to describe the creep behavior of the material as a function of both age and temperature. The results show that the effect of physical aging is to progressively reduce the level of the relaxed beta compliance and increase the mean retardation time of the glass-rubber alpha relaxation process. The effect of conducting creep tests on specimens of the same age at progressively higher temperatures has the opposite effect; the level of the relaxed beta compliance increases while the mean retardation times of the alpha process decrease. Neither the aging rate nor the shape of the distribution of retardation times are affected by temperature. ESA

CREEP AND PHYSICAL AGING OF PVC: DEPENDENCE ON STRESS AND TEMPERATURE

B. E. Read, G. D. Dean, and P. E. Tomlins Jul. 1993 21 p Sponsored by Dept. of Trade and Industry

(ISSN 0959-2423)

(NPL-DMM(A)-115; ETN-94-95507) Copyright Avail: Issuing Activity (National Physical Laboratory, Teddington, Middlesex TW11 0LW, United Kingdom)

On the basis of data obtained for PVC, extensions were made to a model for analyzing the creep compliance curves of glassy, amorphous polymers. Short term data in the alpha region were fitted with a stretched exponential function containing an effective retardation time t(sub 0) which increases with the age of the polymer and decreases with stress and temperature. Physical aging during long term creep gives rise to an increase in t(sub 0) with creep time, the rate of increase depending on stress and temperature. Functions which quantitatively describe these variations in t(sub 0), and which relate the creep compliance to age state, creep time, stress and temperature, were developed. These functions could provide a basis for predicting the creep behavior over wide and continuous ranges of test variables from data acquired in a limited number of tests. ESA

LUBRICANT RHEOLOGY AT HIGH SHEAR RATES Ph.D. Thesis

Ruqiang Feng 1993 242 p

Avail: Univ. Microfilms Order No. DA9313361

The rheological response of lubricants may become non-Newtonian at high shear rates. The constitutive modeling of such a behavior relies upon the results of high-rate rheological experiments. Substantial viscous heating is always a concern in high-rate rheometry; proper experimental techniques are crucial for obtaining valid measurements of material properties. In this study, a short-time high-rate rheometer is developed using the torsional Kolsky bar technique. A thin layer of lubricant, held between concentric cylinders, is sheared at shear rates up to 4 x 10(exp 4) s(exp -1) for times on the order of 10(exp 2) microsec, and for a range of temperatures. For these short times, the total work done in shearing a lubricant is small; therefore the experimental results are expected to provide constitutive information that is minimally affected by shear heating. Next, a computational scheme is developed to solve the full transient thermo-mechanical problem involved in simple shear rheometry with fully nonlinear constitutive relations and with realistic thermal boundary conditions (including the effect of conduction in the surrounding metal parts). The numerical simulation of the Kolsky bar rheometer suggests that the experimental technique can be used to obtain the rheological properties of lubricants at high shear rates, and that the temperature rise in the lubricant layer can be estimated accurately using the experimental results and adiabatic conditions only. Numerical simulations are also conducted for long-time thin-film rheometry experiments, which provide most of the experimental data that supports the current understanding of the high-rate rheology of lubricants. The computations suggest that, in long-time thin-film rheometry, the commonly used isothermal boundary for the lubricant layer is inadequate, although the temperature rise in the film does decrease significantly with decreasing film thickness. Other critical issues in high-rate rheometry, including the rise time of the boundary velocity, the instability of the shear flow, and the influence of film thickness in short-time rheometry, are studied through numerical simulations. The limitations of wing rheometers to explore high-rate rheology are discussed in the light of the results of these numerical simulations. Dissert. Abstr.

N94-29975 Brown Univ., Providence, RI.

MICROMECHANICS OF THE DYNAMIC RESPONSE OF CERAMICS AND CERAMIC COMPOSITES Ph.D. Thesis

Horacio Dante Espinosa 1992 237 p

Avail: Univ. Microfilms Order No. DA9308802

In this investigation we performed plate impact experiments to study the evolution of damage in ceramics and ceramic composites by subjecting the specimen to stress pulses which are large enough in amplitude to initiate microcracks, but short enough in duration to prevent their coalescence into macrocracks. In the 'soft-recovery' experiment, a star-shaped flyer plate impacts a square specimen which has a square impedance-matching 'momentum trap' behind it. The size and shape of these three plates is such that the central portion of the specimen can be subjected to compressive and tensile stress pulses, which are controllable in magnitude and duration, and which allow the specimen to be recovered for microstructural analyses. Through the use of a laser interferometer, these pulses are monitored and used to determine the validity of proposed models. The recovered specimens are examined using transmission electron microscopy (TEM) and scanning electron microscopy (SEM) to determine the pattern of microcracks for comparison with the predictions of the assumed models. In spite of many contributions to the field of damage induced by compressive waves, lack of consensus on the mechanisms responsible for the measured velocity profiles still remains. Our observations seem to unequivocally point to deformation in the intergranular glassy phase as a major mechanism of inelasticity in ceramics subjected to compressive dynamic loading. The possibility of compressive cracking, an alternative candidate mechanism, is ruled out by the observed absence of retardation of waves traveling through regions of the specimen previously deformed in compression. In addition, the recorded compressive pulse profiles strongly suggest a deformation by 'areal slip' i.e., by interfacial sliding over an expanding area. A detailed finite element analysis of the glass/grain-junction system has revealed that the stress concentration is sufficient to induce plastic flow in the glass under the conditions of our experiments. The numerical simulations demonstrate the ability of the areal slip model to reproduce all the salient features of the experimental record over a wide range of impact velocities. In tension, microcracking is identified as the principal inelastic mechanism. Microcrack growth is modeled using standard relations of dynamic fracture mechanics. Because dynamic crack-tip equations of motion are differential equations of first order in time, the overall response under dynamic tensile loading is of the viscoplastic type. Our simulations demonstrate that the dilute approximation is valid over a wide range of the material response. Dissert. Abstr.

Mo-Si-N films with a high nitrogen concentration were produced by sputter-deposition in nitrogen plasma. Chemical composition was determined with Rutherford backscattering and nuclear reaction analysis. Ratio of Mo to Si was 1:2 in the coatings with a nitrogen concentration of 50%. Microstructure of the as-deposited coatings on a silicon substrate was amorphous and no crystallization was found after annealing up to 1000 deg C, although some relaxation was observed in X-ray diffraction. This was confirmed by high-resolution TEM. Hardness of Mo-Si-N films was 18.8 GPa as determined with a nanoindenter. This is significantly higher than that of MoSi2 films, 11.2 GPa. Hardness of the Mo-Si-N films increased to 24.4 GPa after annealing at 800 deg C, which is the same as that of the tetragonal phase of MoSi2, 25.5 GPa. Similarly, modulus of as-deposited Mo-Si-N film was higher (257 GPa) than that of MoSi2 film (222 GPa). However, only a slight increase in the modulus of the Mo-Si-N film was found after annealing at 800 deg C, whereas the modulus of the crystallized tetragonal MoSi2 was 382 GPa. No cracking was found in the Mo-Si-N films even after annealing at 1000 deg C. DOE

STUDY OF THE ULTRAVIOLET ABSORPTION AND PHOTOCONDUCTION SPECTRA OF POLYIMIDE FILMS FABRICATED AT VARIOUS CURING TEMPERATURES M.S. Thesis
Lin Kan Aug. 1993 84 p
(ISBN-0-315-85923-7; CTN-94-61172) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The absorption and photoconduction spectra in the ultraviolet region for polyimide films fabricated under various curing temperatures were measured. There are four absorption peaks located at 3.65, 4.35, 5.65, and 6.40 eV in the fully cured polyimide films. The 6.40 eV peak is practically independent of the curing temperature, but the other three peaks increase with increasing curing temperature. These four peaks are due to intra- and intermolecular optical transitions. In the photoconduction quantum efficiency spectra, there are also four peaks in the fully cured polyimide films: 3.55, 4.05, 4.90, and 5.80 eV. Analysis of the photoconduction quantum efficiency spectra yields values of 4.17 and 4.37 eV as the potential barrier heights for photoemission from Au and Ag electrodes to polyimide, respectively. The quantum efficiency increases with increasing applied electric field, following closely the Onsager theory with a thermalization separation 30 Angstroms in the ultraviolet region. The primary yield increases with increasing curing temperature. Author (CISTI)

ABLATION OF POLYMERS BY ULTRAVIOLET PULSED LASER
A. Brezini (Oran Univ., Es-Senia, Algeria.), N. Benharrats, and F. Hamdache Aug. 1993 59 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-608100; IC-93/264) Avail: CASI HC A04 (US Sales Only)

The surface modifications of different polymers treated by far UV-excimer laser (lambda = 193, 248, and 308 nm) are analyzed by x ray photoelectron spectroscopy. The main feature observed depends strongly on the absorption coefficients. For the high absorbing polymers (e.g., polystyrene, polyimide), the mechanism of the UV-excimer laser interaction appears to be governed by an ablative photodecomposition process (APD) with an APD threshold. In the other limit, i.e. low absorbing polymer, the interaction leads to a photothermal process. DOE

(DE94-005095; SAND-93-1457C; CONF-940412-2) Avail: Issuing Activity (Department of Energy (DOE))

A study aimed at testing the Arrhenius life prediction approach is described. After aging elastomeric materials at several elevated (accelerated) temperatures, a modulus profiling apparatus was used to demonstrate the complicated diffusion-limited oxidation anomalies are typically present under accelerated oven-aging conditions. By using surface modulus results (oxidation less to a monotonic increase in modulus), estimates are made of the true activation energy (E(sub a)) appropriate to the oxidation reactions dominating degradation. Even though macroscopic properties should be influenced by the diffusion-limited oxidation complications, ultimate tensile elongation results were found to be correlated to the true E(sub a). This implies that cracks initiate at the hardened surface of the material and then quickly propagate through the less oxidized interior. If values of E(sub a) obtained from accelerated exposures can be determined and rationalized, another important question involves the Arrhenius assumption that E(sub a) remains constant in the extrapolation region. Preliminary data from two ultra-sensitive techniques (oxygen consumption and microcalorimetry) aimed at testing this fundamental assumption are described. DOE

PLASMA ENHANCED CHEMICAL VAPOR DEPOSITION OF ZrO2 THIN FILMS Ph.D. Thesis
K. Saravanan Dec. 1993 129 p
(Contract W-7405-eng-82)
(DE94-006031; IS-T-1424) Avail: CASI HC A07/MF A02

Amorphous ZrO2 thin films were deposited in an inductively coupled PECVD system using a Zr beta-diketonate, Zr(C11H19O2)4, as the precursor. The deposits were air annealed at 900 C for 5 min to get pure, single phase, oriented, polycrystalline alpha-ZrO2. Feasibility of using 2 different types of reactors was investigated. The inductively heated horizontal reactor depositions at 600 C had a lower deposition rate and the films were non-uniform in thickness with a columnar structure. The resistively heated vertical reactor depositions at 350 C had a higher deposition rate and the films were more uniform in thickness with a fine grained microstructure. The statistical design was demonstrated as an effective technique to analyze the effect of process conditions on the rate of deposition and relative (h00) orientation. The factorial design was used to quantify the two responses in terms of the process variables and their mutual interactions. The statistical design for rate of deposition was found to correlate with the trends observed in classical design. DOE

This work presents the results of the X-Ray Photoelectron Spectroscopy (XPS) analysis of AISI 440C ball surfaces lubricated with perfluoropolyether (PFPE) oils after friction experiments under sliding conditions at high load in air and vacuum environments. The PFPE lubricants tested were Demnum S100, Fomblin Z-25, and Krytox 143AB. It was found that all the PFPE lubricants were degraded by sliding contact causing the formation of inorganic fluorides on the metallic surfaces and a layer of organic decomposition products. KRYTOX 143AB was the least reactive of the three lubricants tested. It was also found that metal fluoride formed at off-scar areas. This suggests the formation of reactive species, such as COF2 or R(sub f)COF, during sliding experiments, which can diffuse through the lubricant film and react with the metallic surfaces away from the contact region. Comparison of reference specimens before sliding with those that had undergone the sliding tests showed that the amount of non-degraded PFPE remaining on the surface of the balls after the sliding experiments was greater than that of the balls without sliding. Author (revised)

EFFECTS OF HYDROGEN ON THE RESISTIVITY OF THIN Au AND Cu FILMS Ph.D. Thesis
Christopher Alan Apblett 1992 239 p
Avail: Univ. Microfilms Order No. DA9314340

The effect of hydrogen on the resistivity of thin (200 nm) gold and copper films has been studied. Hall effect measurements were used to determine if the observed change in resistivity was due to electron density or electron mobility. Measurements of the time dependence of resistivity changes were used to determine the kinetics of the resistivity change caused by hydrogen, and the influence of the substrate on the resistivity change. Measurements of resistivity as a function of hydrogen pressure were used to determine the type of hydrogen adsorption occurring on the surface of the films. Hydrogen was found to raise the mobility of conduction electrons in a metal. The change in the mobility was found to decrease with prior annealing. The kinetics of the resistivity change in vacuum indicated an interface limited reaction, subject to the geometrical constraint of a spherical moving interface. The activation energy for the vacuum annealing was 0.2 +/- 0.1 eV in gold and 0.3 +/- 0.15 eV in copper. In hydrogen annealing, the kinetics were diffusion limited with the same geometry constraint. The activation energy of the hydrogen annealing was 0.06 +/- 0.04 eV in gold and 0.05 +/- 0.04 eV in copper, consistent with the diffusion of hydrogen through a lattice. It was concluded that hydrogen may have assisted in the motion of scattering defects to a grain boundary or free surface. This would increase the mean free path length of the electrons through the metal and lower the resistivity. Hydrogen was found to adsorb as the molecule on gold or copper surfaces and the adsorption followed the Langmuir isotherm. Dissert. Abstr.

NON-AQUEOUS CLEANING SOLVENT SUBSTITUTION
G. J. Meier Jan. 1994 11 p Presented at the 4th National Technology Transfer Conference and Exposition, Anaheim, CA, 7-9 Dec. 1993
(Contract DE-AC04-76DP-00613)
(DE94-005339; KCP-613-5345; CONF-931244-1) Avail: CASI HC A03/MF A01

A variety of environmental, safety, and health concerns exist over the use of chlorinated and fluorinated cleaning solvents. Sandia National Laboratories, Lawrence Livermore National Laboratories, and the Kansas City Division of Allied Signal have combined efforts to focus on finding alternative cleaning solvents and processes which are effective, environmentally safe, and compliant with local, state, and federal regulations. An alternative solvent has been identified, qualified, and implemented into production of complex electronic assemblies, where aqueous and semi-aqueous cleaning processes are not allowed. Extensive compatibility studies were performed with components, piece-parts, and materials. Electrical testing and accelerated aging were used to screen for detrimental, long-term effects. A terpene, d-limonene, has been selected as the solvent of choice, and has been found to be compatible with the components and materials tested. A brief history of the overall project will be presented, along with representative cleaning efficiency results, compatibility results, and residual solvent data. The electronics industry is constantly searching for proven methods and environmentally safe materials to use in manufacturing processes. The information in this presentation will provide another option to consider on future projects for applications requiring high levels of quality, reliability, and cleanliness from non-aqueous cleaning processes. DAMAGE ANALYSIS AND MECHANICAL RESPONSE OF AS-RECEIVED AND HEAT-TREATED NICALON/CAS-2 GLASS-CERAMIC MATRIX COMPOSITES Ph.D. Thesis
Shin Steven Lee 1993 191 p
Avail: Univ. Microfilms Order No. DA9323777

Experimental results of damage development in and mechanical response of heat-treated Nicalon/CAS-2 laminates subjected to monotonic flexure and axial loading and to cyclic tensile loading are reported. The specimens were subjected to post-processing heat treatments at 900, 1000, and 1100 C in air for 100 hours. Changes at the fiber/matrix interface/interphase due to post-processing heat treatments were also characterized. The combined effect of fiber debonding and transverse matrix cracking in both 90 deg and 0 deg plies plays an important role in damage development in (0/90)(sub 4s), Nicalon/CAS-2 laminates, especially in developing the secondary damage modes such as longitudinal matrix cracking and delamination. Frictional wear effects found in cyclically loaded specimens may be responsible for the observed temperature profiles during the intermediate stage of fatigue life. It is also believed that frictional wear is critical to the failure of notch sensitive fibers. Different damage modes such as 'brittle' matrix crack propagation and 'quasi-brittle' matrix crack propagation were observed in heat-treated specimens. Results obtained from microanalysis using an analytical scanning transmission electron microscope equipped with an energy dispersive spectrometer, and microindentation indicated that the changes of damage and failure modes were directly related to the changes of characteristics at the fiber/matrix interface/interphase. Dissert. Abstr.

KINETICS OF SURFACE ROUGHENING AND SMOOTHING DURING ION SPUTTERING
E. Chason, T. M. Mayer, and A. J. Howard 1993 12 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-76DP-00789)
(DE94-006358; SAND-93-1447C; CONF-931108-64) Avail: CASI HC A03/MF A01

We have measured the kinetics of roughness evolution during low energy ion sputtering of SiO2 surfaces using in situ x-ray reflectivity. Sputtering with heavy ions (Xe) leads to rapid roughening of the surface that can not be explained by a simple random removal process. Subsequent bombardment with light ions (He,H) leads to an exponential decrease in the surface roughness. These kinetics are explained quantitatively by a linear model that contains a balance between smoothing by surface diffusion and viscous flow and roughening by sputter removal of material. A curvature dependent sputter yield leads to amplification of a limited range of spatial frequencies on the surface and the formation of a ripple topography. DOE

CHARACTERIZATION OF THERMALLY ANNEALED Sb IMPLANTED FUSED SILICA
S. H. Morgan (Fisk Univ., Nashville, TN.), Z. Pan (Fisk Univ., Nashville, TN.), D. O. Henderson (Fisk Univ., Nashville, TN.), S. Y. Park (Vanderbilt Univ., Nashville, TN.), R. A. Weeks (Vanderbilt Univ., Nashville, TN.), R. H. Magruder, III (Vanderbilt Univ., Nashville, TN.), and R. A. Zuhr Dec. 1993 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE94-005464; CONF-931108-44) Avail: CASI HC A02/MF A01

The local environment of the polarizable ion in heavy metal oxide glasses is postulated to strongly influence the nonlinear response of these materials. The authors have previously observed that post-implantation thermal annealing changes the chemical properties of the implanted layer in a different fashion in Pb- and Bi- implanted SiO2. In this paper the authors report the optical behavior of Sb-implanted SiO2 as a function of annealing temperature and atmosphere. High purity fused silica substrates were implanted at room temperature to a dose of 6 x 10(exp 16) ions/cm(exp 2), and subsequently annealed at temperatures from 500 to 1000 C in argon and oxygen atmospheres. RBS, optical absorption (1.8 to 6.2 eV), infrared reflectance (450 to 5000 cm(exp -1)), and nonlinear index of refraction were measured before and after annealing. The results of these measurements indicate that annealing treatment significantly affects the local environment of the implanted Sb ions, and consequently the optical response. DOE

CENTRIFUGAL ATOMIZATION OF LANTHANIDE MATERIALS FOR CRYOGENIC COOLERS Ph.D. Thesis
M. G. Osborne Jan. 1994 106 p
(Contract W-7405-eng-82)
(DE94-006035; IS-T-1679) Avail: CASI HC A06/MF A02

Until recently, Pb was the preferred heat exchanger matrix material used in low temperature cryocoolers; however, the heat capacity of Pb drops drastically below approximately 15 K and new matrix materials based on the lanthanide elements were developed. These materials magnetically order at low temperatures and the entropy change associated with ordering contributes to the materials' heat capacities. The drawback to widespread use of lanthanide intermetallic compounds in cryocoolers has been the difficulty in manufacturing high-quality particulates. The purpose of this project was to develop a technique for producing high-quality powders of

lanthanide metals and lanthanide intermetallic compounds for use in cryocooler heat exchangers. A series of atomization experiments was performed using Er3Ni, Nd, Nd3Ni, and (Er(0.5)Nd(0.5))(3)Ni. Atomization of these materials resulted in particles ranging from mostly spherical to extremely flattened. Analyses of size distributions for the experiments indicate that increased atomization disk speed and superheat result in smaller mean particle diameters and narrower size distributions. Chemical analyses of the atomized powders indicate that the CA/RQB technique produces particulate with much lower interstitial contamination than other techniques. The Er3Ni and Nd3Ni powders were predominantly of the desired phase and the (Er(0.5)Nd(0.5))(3)Ni powder had one major and possibly three minor phases. The solidification morphology is typically fine dendritic or cellular with finer microstructure spacings near the particle surfaces. The Er3Ni powders have higher heat capacities than gas atomized powders reported in literature. The heat capacity of Nd3Ni has a peak which does not degrade dramatically with processing. The (Er(0.5)Nd(0.5))(3)Ni material has a higher heat capacity compared to Er3Ni, Nd3Ni, and Nd at temperatures above 10K. DOE

EVALUATION OF CORROSION PROTECTING PROPERTIES OF MODERN AIRCRAFT PAINT SYSTEMS

W. G. J. tHart and J. A. M. Boogers Dec. 1991 32 p Presented at the Aerospace Corrosion Control Symposium, Amsterdam, Netherlands, 23-25 Mar. 1992 Sponsored by Royal Netherlands Air Force Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B179388; NLR-TP-91460-U; ETN-94-95958) Avail: CASI HC A03

The flexibility, adhesion and corrosion protecting properties of several modern paint systems were examined. Since paint cracking around fasteners under operational conditions usually occurs at low temperatures, this was examined by tensile testing of painted metal strips at -50C. After tensile testing the degree of paint delamination (loss of adhesion) was established, and cross sections were made to examine this delamination on a microscopic scale. The corrosion protecting capability of paint systems was determined by exposing specimens with a precracked paint system and crossed scribe lines to an accelerated corrosion test (MASTMAASIS). In this investigation the different paint systems had the same topcoat, Aerodur HF A 132. Since Plastic Media Blasting (PMB) is a potential method for replacing the chemical paint stripping procedure, PMB and various cleaning operations were also considered. ESA

PROPERTIES OF CHEMICAL VAPOR INFILTRATION DIAMOND DEPOSITED IN A DIAMOND POWDER MATRIX

J. K. G. Panitz, D. R. Tallant, C. R. Hills, and D. J. Staley 1993 21 p Presented at the 40th National Symposium of the American Vacuum Society (AVS), Orlando, FL, 15-19 Nov. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC04-94AL-85000)

(DE94-005429; SAND-93-2594C; CONF-9311104-19) Avail: CASI HC A03

Densifying non-mined diamond powder precursors with diamond produced by chemical vapor infiltration (CVI) is an attractive approach for forming thick diamond deposits that avoids many potential manufacturability problems associated with predominantly chemical vapor deposition (CVD) processes. The authors have developed two techniques: electrophoretic deposition and screen printing, to form non-mined diamond powder precursors on substrates. They then densify these precursors in a hot filament assisted reactor. Analysis indicated that a hot filament assisted chemical vapor infiltration process forms intergranular diamond deposits with properties that are to some degree different from predominantly hot-filament-assisted CVD material. MATERIALS COMPATIBILITY AND LUBRICANTS RESEARCH ON CFC-REFRIGERANT SUBSTITUTES

S. R. Szymurski, G. C. Hourahan, and D. S. Godwin Oct. 1993 44 p

(Contract DE-FG02-91CE-23810)

(DE94-004905; DOE/CE-23810/22) Avail: CASI HC A03/MF A01

The Materials Compatibility and Lubricants Research (MCLR) program supports critical research to accelerate the introduction of CFC and HCFC refrigerant substitutes. The MCLR program addresses refrigerant and lubricant properties and materials compatibility. The primary elements of the work include data collection and dissemination, materials compatibility testing, and methods development. The work is guided by an Advisory Committee consisting of technical experts from the refrigeration and air-conditioning industry and government agencies. The Air-Conditioning and Refrigeration Technology Institute, Inc., (ARTI) manages and contracts multiple research projects and a data collection and dissemination effort. Detailed results from these projects are reported in technical reports prepared by each subcontractor. DOE

THE POLYMERIZATION OF EPSILON-CAPROLACTONE WITH STANNOUS CATALYST AND LACTIDE/EPSILON-CAPROLACTONE (LA/EPSILON-CL) AND LACTIDE/GLYCOLIDE (LA/GA) COPOLYMERS. POLYMER TECHNOLOGY PUBLICATION SERIES NO. 15 Literature Review

I. Ylikangas and M. Hiljanen 1993 71 p

(ISSN 0785-7144)

(PB94-137551; ISBN-951-22-1699-X) Avail: CASI HC A04/MF A01

The purpose of the first literature search was to report the published studies on tin catalysts of the polymerization of epsilon-caprolactone (epsilon-CL) monomer. The caprolactone represents an interesting system that can be polymerized with the anionic and coordination catalysts as well as cationic systems. The anionic polymerization of epsilon-CL may be catalyzed by alkoxide catalysts and is complicated by inter- and intramolecular transesterification reactions that give rise to a mixture of linear and cyclic material and broad molecular weight distributions. The second literature study concentrates on lactide/epsilon-CL and lactide/glycolide copolymers obtained by ring polymerization in the presence of stannous octoate as catalyst. Derived from text

NORMAL STATE RESISTIVITY OF MBa2Cu3O(7-x) CERAMICS

C. Sulkowski, N. M. Vladimirova, V. M. Drobin, K. Rogacki, and Z. Damm 1992 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DE94-608456; JINR-R-14-92-65) Avail: CASI HC A02 (US Sales Only)

The precision temperature dependences of resistivity p(T) for ceramic samples MBa2Cu3O(7-x) where M is Y, Er, Eu, Gd, Ho, Dy, Er+Y were measured. The samples with high concentration of oxygen (i.e. with low p) showed clear deviation p(T) from linear dependence below 260-270 K. This deviation (Delta)p is positive and its value decreases with decreasing oxygen concentration and arrives (Delta)p=0 for x=0.2. Another factor decreasing value p appearing below 200 K is fluctuation superconductivity. Its contribution was defined for the sample with (Delta)p=0 and accounted in calculation of normal state resistivity p(sub n)(T). Resulted p(sub n)(T) in the range 120-300 K for samples with oxygen concentration close to 7 is typically metallic and agree with classic Bloch-Crueneisen theory. DOE

SILICA SCINTILLATING MATERIALS PREPARED BY SOL-GEL METHODS

D. W. Werst, M. C. Sauer, Jr., K. R. Cromack, Y. Lin, E. A. Tartakovsky, and A. D. Trifunac 1993 8 p Presented at the SCIFI 1993 Workshop on Scintillating Fiber Detectors, South Bend, IN, 24-28 Oct. 1993

(Contract W-31-109-eng-38)

(DE94-005123; ANL/CHM/CP-81640; CONF-9310261-2) Avail: CASI HC A02/MF A01

Silica was investigated as a rad-hard alternative to organic polymer hosts for organic scintillators. Silica sol-gels were prepared by hydrolysis of tetramethoxysilane in alcohol solutions. Organic dyes were incorporated into the gels by dissolving in methanol at the sol stage of gel formation. The silica sol-gel matrix is very rad-hard. The radiation stability of silica scintillators prepared by this method is dye-limited. Transient radioluminescence was measured following excitation with 30 ps pulses of 20 MeV electrons. DOE

CONTROLLING THE MATERIAL PROPERTIES OF IN VITRO COLLAGEN THROUGH DIRECTED ORIENTATION AND CROSS-LINKING OF FIBRILS Ph.D. Thesis
Todd Edward Bergren 1993 103 p
Avail: Univ. Microfilms Order No. DA9320397

Collagen is a polymeric, fibrillar protein and is the main constituent of all tensile load bearing structures in vivo. Under the proper laboratory conditions, collagen can be dissolved and reassembled into fibers. However, in vitro collagenous constructs have none of the exquisite organization found in in vivo collagen structures. This organization gives in vivo products the propitious material properties (e.g., tensile strength) they exhibit. As a surgical implant material, collagen produced in vitro shows great promise, evincing a low immune response and permitting the infiltration of in vivo collagen. However, in vitro collagenous products lack the material properties of in vivo collagen. It was the purpose of this study to develop methods through which in vitro collagen with more desirable material properties may be produced. Two general methods of increasing the strength of collagen were used, controlling the organization of the in vitro material and increasing the crosslinking of the product. New methods of crosslinking were developed to produce a material with the strength of collagen fixed with glutaraldehyde, but with lower immunogenicity. Collagen strings were extruded from glass tubes into a buffer bath in which the monomers assembled into fibrils. It was believed that the shear gradient of the Poiseuille flow set up in the tubes would force alignment on the collagen molecules in the solution. It was hoped that the final reassembled product would exhibit the longitudinal organization imposed on the molecules in solution. The effects of varying Reynold's number and tube diameter on the final product were tested. The strings were mechanically tested and the material parameters thus obtained (i.e., elastic modulus (Y), ultimate tensile strength (UTS)) analyzed. No significant differences from the controls were found for the fixed samples. Significant increases in Y and UTS were found as Re was increased. An increase in the extrusion tube diameter produced significant decreases in Y and UTS. Scanning electron microscopy supported the conclusion that changes in fibrillar organization were induced by shear flow. An attempt was made to organize collagen during assembly in microgravity through the use of isoelectric focusing of tropocollagen molecules. Histological examination revealed no orientation differences between flight and ground. Dissert. Abstr.

N94-30812 North Dakota State Univ., Fargo.
CROSSLINKING AND SURFACE REACTIONS IN MACROMOLECULES: SPECTROSCOPIC FT-IR STUDIES Ph.D. Thesis
Scott Richard Gaboury 1993 212 p
Avail: Univ. Microfilms Order No. DA9321837

Studies were undertaken to advance our knowledge and to gain new insights about macromolecular crosslinking systems and plasma surface reactions on crosslinked polymers. Analysis of polymeric networks was carried out using Fourier transform infrared (FT-IR) spectroscopic methods, including transmission, photoacoustic (PA), and attenuated, total reflectance (ATR) FT-IR modes of detection. The crosslinking reactions of hydroxyl terminated poly dimethyl siloxane (PDMS) were studied using PA FT-IR spectroscopy and involved the analysis of evolved ethanol. Intensity changes of the ethanol bands were correlated to the viscosity measurements. Transmission FT-IR was found to be insensitive to the crosslinking reactions. PA and transmission FT-IR spectroscopy were also used to elucidate the origin of crosslinking reactions in polyester/styrene (PE/ST). Gelation and vitrification transitions in PE/ST were detected spectroscopically and the formation of atactic polystyrene during crosslinking was revealed. ATR FT-IR spectroscopy was utilized to study the effects of different plasma surface reactions on silicone elastomers. Ammonia plasma reactions of PDMS containing chloro-functional initiators or cleaning solvents resulted in the formation of surface amide groups, but due to the parallel formation of surface ammonium chloride, the amide groups were not chemically bound to the PDMS surface. A novel microwave plasma reactor was developed and used for plasma modification of PDMS elastomer surfaces. Analysis of the ATR spectra revealed the presence of Si-H surface functional groups that were produced by both argon and nitrogen plasmas. The use of a Kramers-Kronig transformation allowed quantitative analysis of the Si-H concentrations. Acrylamide and maleic anhydride solid monomers were microwave plasma reacted onto PDMS elastomers. Plasma reactions, ranging from approximately 5 to 15 seconds, caused maleic anhydride and acrylamide to be chemically bound to the PDMS surface, while the majority of anhydride and amide functionalities were maintained. Quantitative analysis of ATR FT-IR spectra showed that the surface concentrations of solid monomers ranged from 1 to 5 picomole/sq cm. Such functionalized PDMS surfaces can be post plasma reacted using base hydrolysis. The hydrolysis of the amide and anhydride functionalities to carboxylic acid salt groups yielded a 66 percent conversion for acrylamide and a 48 percent conversion for maleic anhydride. Dissert. Abstr.

DUAL CURE LOW-VOC COATING PROCESS, PHASE 3
K. E. Kinzer Nov. 1993 20 p
(Contract DE-AC04-88ID-12692)
(DE94-003202; DOE/ID-12692/5-Phase-3) Avail: CASI HC A03/MF A01

The objective of Phase 3 is to complete proof-of-principle testing in full-scale systems of the dual cure photocatalyst technology developed in earlier phases. Phase 3 commercial applications are aerospace topcoats, aerospace primers, and solventless manufacture of tape backings. Progress was made in improving urethane/acrylate formulation for aerospace topcoats, particularly in reverse impact, initial gloss, and loss retention during accelerated weathering. Formulations have now been developed which meet all initial criteria; the formulation was optimized. Aerospace primer formulations based on epoxy/flexibilizer systems were evaluated. Because of cure consistency problems and the increased need for non-chromated primers, work on aerospace primer system was de-emphasized to allow greater effort on development and commercialization of aerospace topcoat. Work on solventless backing saturants for electrical tape backings has been completed; optimal dual cure resin formulations have been used in preparing complete tape constructions. DOE

MATERIAL PROPERTIES AND FRACTURE MECHANICS IN RELATION TO CERAMIC MACHINING
L. V. Griffith 2 Dec. 1993 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-006623; UCRL-ID-115689) Avail: CASI HC A03

Material removal rate, surface finish, and subsurface damage are largely governed by fracture mechanics and plastic deformation, when ceramics are machined using abrasive methods. A recently published model describes many of the most important features of the loose abrasive machining process, for example depth of damage, surface roughness, and material removal rate. Many of the relations in the loose abrasive machining model can be readily discerned from fracture mechanics models, in terms of material properties. By understanding the mechanisms of material removal, from a material properties perspective, a better estimation can be made of how one material will machine in relation to another. Although the fracture mechanics models may have been developed for loose abrasive machining, the principles of crack initiation and propagation are equally valuable for fixed abrasive machining. This report provides a brief review of fracture in brittle materials, the stress distribution induced by abrasives, critical indenter loads, the extension of cracks, and the relation of the fracture process to material removal. SURFACE CHEMISTRY OF BORON-DOPED SiO2 CVD: ENHANCED UPTAKE OF TETRAETHYL ORTHOSILICATE BY HYDROXYL GROUPS BONDED TO BORON
M. E. Bartram and H. K. Moffat 1993 6 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC04-94AL-85000)
(DE94-005428; SAND-93-1497C; CONF-931108-41) Avail: CASI HC A02/MF A01

Insight into how dopants can enhance deposition rates was obtained by comparing reactivities of tetraethyl orthosilicate (TEOS, Si(OCH2)CH3(sub 4)) with silanol and boranol groups on SiO2. This comparison is relevant for boron-doped SiO2 film growth from TEOS and trimethyl borate (TMB, B(OCH3)(sub 3)) sources since boranols and silanols are expected to be

present on surface during CVD. A silica substrate having coadsorbed deuterated silanols (SIOD) and boranols (BOD) was reacted with TEOS in a cold-wall reactor in the mTorr pressure regime at 1000 K. Reactions were followed with Fourier transform infrared spectroscopy. Use of deuterated hydroxyls allowed consumption of hydroxyls by TEOS chemisorption to be distinguished from concurrent formation of SIOH and BOH that results from TEOS decomposition. It was found that TEOS reacts with BOD at twice the rate observed for SIOD demonstrating that hydroxyl groups bonded to boron increase the rate of TEOS chemisorption. Surface ethoxy groups produced by chemisorption of TEOS decompose at a slower rate in the presence of TMB decomposition products. Possible dependencies on reactor geometries and other deposition conditions may determine which of these two competing effects will control deposition rates. This may explain (in part) why the rate enhancement effect is not always observed in boron-doped SiO2 CVD processes. DOE

MEASUREMENT OF BULK LONGITUDINAL MODULUS AND CORRECTION FOR EDGE EFFECTS
D. J. Segalman and S. E. Klenke 1993 13 p Presented at the North American Conference on Smart Structures and Materials, Orlando, FL, 13-18 Feb. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005581; SAND-93-2058C; CONF-940206-2) Avail: CASI HC A03/MF A01

Measurement of the bulk longitudinal modulus, M(sup *), of rubbery polymers is a notoriously difficult task. Measurements are traditionally done through a fluid environment in methods that provide M(sup *) over only very narrow frequency ranges. An alternative approach, using a resonant test fixture is presented in this paper. A discussion of some physical limitations is developed. Among them are issues of repeatability and edge effects. A method of data analysis to address edge effects is also presented. DOE

AN ASYMPTOTIC ANALYSIS FOR COMPRESSIBLE GAS LUBRICATION OF ROUGH SURFACES Ph.D. Thesis
Ki Ook Park 1993 134 p
Avail: Univ. Microfilms Order No. DA9319604

The lubrication of a magnetic head on a rough computer hard disk with compressible gas was modeled by applying an asymptotic analysis. The basic equations were derived from the general conservation equations by means of a perturbation technique using the fluid film thickness-to-length ratio as the small parameter. The analysis focuses on hydrodynamic flow; therefore, elastic deformation of the general bearing surface and even partial asperity contact do not occur. The asymptotic analysis for Reynolds roughness and Stokes roughness uses the continuity and the Navier-Stokes equations. The analysis considers a sufficiently thick gas bearing condition such that air is taken to be a continuous gas but a sufficiently thin film so that roughness effects are significant. Temperature, compressibility, moving-roughness, and Stokes-roughness effects are described. Inertia and temperature effects were found to be not very important. The compressibility effect is presented as the pressure dip at the trailing edge of gas bearing. A deeper pressure dip is detected in the moving roughness models because of the unsteady squeeze effect of moving roughness. The lowest-order equations are reduced to the well-known Reynolds equation and the limit of conventional lubrication analysis can be also seen by the direct comparisons between the zeroth- and second-order solutions.

IMPACT STUDY ON THE USE OF BIOMASS-DERIVED FUELS IN GAS TURBINES FOR POWER GENERATION
C. A. Moses and H. Bernstein Jan. 1994 132 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000261; NREL/TP-430-6085) Avail: CASI HC A07/MF A02

This report evaluates the properties of fuels derived from biomass, both gaseous and liquid, against the fuel requirements of gas turbine systems for generating electrical power. The report attempts to be quantitative rather than merely qualitative to establish the significant variations in the properties of biomass fuels from those of conventional fuels. Three general categories are covered: performance, durability, and storage and handling. DOE

ALTERNATIVE FUEL VEHICLES FOR THE STATE FLEETS: RESULTS OF THE 5-YEAR PLANNING PROCESS
May 1993 121 p Sponsored by DOE
(DE94-004709; DOE/EE-0007) Avail: CASI HC A06/MF A02

This report documents the first attempt by the Department of Energy (DOE) to work with states to prepare five-year Alternative Fuel Vehicle (AFV) acquisition plans to identify alternative fuels and vehicles that they are planning on or would like to acquire. The DOE Regional Support Offices (RSO's) met with representatives from the states in their regions and assisted in the preparation of the plans. These plans will be used in conjunction with previously gathered Federal five-year plans to encourage Original Equipment Manufacturers (OEM's) to expand the variety of AFV's produced, reduce the incremental cost of AFV's, and to encourage fuel suppliers to expand the alternative fuel infrastructure and alternative fuel availability. By identifying the needs and requirements of state fleets, DOE can begin to describe the specific nature of the future state fleets, and establish a defined market for OEM's and fuel suppliers. DOE initiated the development and collection of the state five-year plans before the signing of the Energy Policy Act, to raise the awareness of states that they will be required by law to acquire AFV's. As a result, several states that had no AFV acquisition plan when queried have developed or are in the process of developing plans. The DOE and its RSO's are still working with the states to develop and refine acquisition plans, and this report should be treated as documentation of work in progress. DOE

FEASIBILITY STUDY ON INTRODUCTION OF A LARGE METHANOL ENGINE POWER GENERATION PLANT
Mar. 1993 116 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-732338; NEDO-P-9224) Avail: CASI HC A06

This paper studies a possibility of introducing a 2-cycle methanol diesel engine power generation plant. Since methanol is much in vaporizing latent heat and small in quantity of heat emission per unit weight when using it as fuel, observed are a decline in combustible range temperature and a large decrease in NOx emissions. As for thermal efficiency, generating end efficiency of 46% is expected by heat recovery in the case of 40-50 thousand kW class 2-cycle engines. The methanol engine has such excellent performance characteristics as little lowering of efficiency at middle loads, possible numerical control, short starting time and high load change rate. The construction cost is approximately equal to that of the LNG steam power generation and is lower than that of the LNG combined cycle power generation. The unit power generation cost is lower than those of fuel cells and gas turbines and 2-3 yen/kW higher than those of the combined cycle and the reformed turbines. DOE

(AD-A275607; ARO-26106.23-CH) Avail: CASI HC A03

We have carried out a research program to investigate the chemical dynamics of unimolecular reactions in large polyatomic molecules. The purpose of the studies is an improved understanding of the fundamental behavior of highly excited, reactive molecules, with an emphasis on energetic materials. We have made some significant progress in extending theoretical chemical dynamics calculations to reactions in large molecules, as illustrated by our explicit, full-dimensional classical dynamics study of the unimolecular decomposition of RDX. Leading up to this study of RDX, we performed a long series of dynamics calculations for a variety of molecules to determine the important factors for accurately simulating processes in polyatomic molecules. A STUDY OF SOLID PROPELLANTS USING A MICROPROBE MASS SPECTROMETER SYSTEM Annual Report No. 1
Thomas A. Litzinger 1993 31 p
(Contract N00014-93-1-0080)
(AD-A275325) Avail: CASI HC A03/MF A01

The objective of this effort is to determine the chemical mechanisms of solid propellant ignition and deflagration with an emphasis on the decomposition of individual propellant ingredients and on the gas phase reactions of the products of decomposition. A quadrupole mass spectrometer system using quartz microprobes measures species profiles above the surface of the sample during CO2 laser induced pyrolysis or during laser assisted deflagration of the sample. In addition microthermocouples are used to measure the surface temperature and gas phase temperatures during testing. To complement the experimental studies, chemical kinetic models produced by other researchers are used to model some of the data obtained. DTIC

(AD-A275248; WL-TR-93-2086) Avail: CASI HC A08

The U.S. Air Force has seen that in order to develop fuels needed for the high performance aircraft of the future, the ability to design fuels based on the satisfaction of a set needed properties is necessary. This report covers all phases of a project to develop software to accomplish this goal. This report discusses the methods used by the software to obtain the thermochemical properties of organic fuel candidates. Emphasis was placed on describing the methods used to determine the properties of a mixture of compounds, since it is these types of mixtures that are most likely to be found in fuels. DTIC

CORRELATION OF COOKOFF BEHAVIOR OF ROCKET PROPELLANTS WITH THERMOMECHANICAL AND THERMOCHEMICAL PROPERTIES
Sook Y. Ho, Tony Ferschl, and John Foureu Nov. 1993 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274983; MRL-TR-93-15; DODA-AR-008-278) Avail: CASI HC A03/MF A01

The fast and slow cookoff behavior of a series of in-service and research composition rocket propellants has been evaluated using the standard small-scale cookoff bomb (SSCB) test (based on the NWC design) as part of a program in Explosives Ordnance Division (EOD) to develop an extensive insensitive munitions technology base. A modified SSCB test methodology, whereby the pressure output can be measured, was developed to enable a more quantitative measure of the reaction violence and to provide further insight into the cookoff mechanism. The temperature

distribution and gradients at various positions and depths in the cylindrical propellant specimen, during fast and slow cookoff, were measured in order to understand the marked difference in the severity of the response shown by some of the propellants when the heating rate was changed. Pressure and heating rate dependent thermochemical properties and thermomechanical properties of the propellants were measured and correlated with cookoff behavior. DTIC

INSENSITIVE ENERGETIC MATERIALS: THE IMPORTANCE OF PHYSICAL PROPERTIES AND MOLECULAR STRUCTURE Final Report, 17 Apr. 1990 - 30 Sep. 1993

Richard Behrens, Jr. 22 Dec. 1993 11 p

(Contract ARO-MIPR-130-93)

(AD-A275393; ARO-27887.6-CH) Avail: CASI HC A03/MF A01

A summary of the most important findings on the thermal decomposition of five cyclic nitramines is presented. The compounds studied include: octahydro-1,3,5,7- tetranitro-1,3,5,7- tetrazocine (HMX), hexahydro-1,3,5-trinitro-striazine (RDX), hexahydro-l-nitroso-3,5- dinitro-s-triazine (ONDNTA), 1,3,5-trinitro- 1,3,5-triazacycloheptane (TNCHP), and 2-oxo- 1,3,5-trinitro-1,3,5-triazacyclohexane (K6). The thermal decomposition processes were studied using simultaneous thermogravimetric modulated beam mass spectrometry (STMBMS) to identify the decomposition products and to determine their gas formation rates and using mixtures of isotopically labeled analogues of the compounds to track the decomposition mechanisms by analyzing the extent of isotopic scrambling and the deuterium kinetic isotope effect (DKIE). Extensive results on the thermal decomposition of RDX and HMX in the solid and liquid phases show that their decomposition is controlled by several parallel decomposition pathways. One pathway involves the loss of HONO and the formation of oxy-s-triazine (OST) from the RDX ring. The other pathway occurs via the mononitroso intermediate of the parent compound. The decomposition of the mononitroso-RDX intermediate, ONDNTA, has been extensively studied and a summary of the highlights of its decomposition is presented. The results on TNCHP show that it is the only one of the cyclic nitramines studied that is stable in the liquid phase. DTIC

THE LASER APPROACH FOR SEQUENTIAL PYROTECHNIC INITIATION SYSTEMS: ENVISAGEABLE CHAIN ARCHITECTURE AND CONCEPTS [SYSTEME SEQUENTIEL D'INITIATION PYROTECHNIQUE PAR LASER: ARCHITECTURE DE CHAINE ET CONCEPTS ENVISAGEABLES]

P. Baraer and J. Masson 1993 24 p In FRENCH Presented at the 7th Institut d'Aeronautique et Spatiale du Canada Conference on Astronautics, Ottawa, Canada, 4-6 Nov. 1992

(Rept-932-430-113; ETN-94-95471) Avail: CASI HC A03/MF A01

The advantages offered by the laser approach for ordnance initiation systems to initiate directly pyrotechnics secondary explosives are described. The basis of light-initiated systems is to develop a unique method that offers the promise of safety in an environment where electromagnetic fields could be a problem. Explosives can be initiated by a wide variety of energy inputs, kinetic energy, electrical discharge, heat, and light. Even if the idea of constructing light initiated systems has been known for 20 years, only recent developments have made their utilization possible. Optical technolgy presents many advantages, most of which concern the optopyrotechnic interface that requires an intense energy which cannot be duplicated by external conditions other than those produced by a specific laser source. Moreover, optical fibers are immune to induced energy from electrical or radio frequency sources, they can survive gamma radiation, and are lighter than metallic cables. The laser ignition program has proved the feasibility of a full chain able to initiate the totality of the pyrotechnic functions in a launcher. The makeup of each component of the pyrotechnic chain is outlined, including the YAG laser, fiber optic distribution system (optomechanical sequencer), and pyrotechnic devices. The characteristics and performances of the ignition device are given. ESA

CATALYTIC IGNITOR FOR REGENERATIVE PROPELLANT GUN Patent Application

Gerald E. Voecks, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and Ned W. Ferraro, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 17 Feb. 1994 21 p

(Contract NAS7-1260)

(NASA-Case-NPO-18987-1-CU; NAS 1.71:NPO-18987-1-CU;

US-Patent-Appl-SN-200785) Avail: CASI HC A03/MF A01

An ignitor initiates combustion of liquid propellant in a gun by utilizing a heated catalyst onto which the liquid propellant is sprayed in a manner which mitigates the occurrence of undesirable combustion chamber oscillations. The heater heats the catalyst sufficiently to provide the activation necessary to initiate combustion of the liquid propellant sprayed thereonto. Two embodiments of the ignitor and three alternative mountings thereof within the combustion chamber are disclosed. The ignitor may also be utilized to dispose of contaminated, excess, or waste liquid propellant in a safe, controlled, simple, and reliable manner. NASA

BIODIESEL FROM AQUATIC SPECIES

L. M. Brown, S. Sprague, E. E. Jarvis, T. G. Dunahay, P. G. Roessler, and K. G. Zeiler Jan. 1994 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DE-AC02-83CH-10093)

(DE94-000275; NREL/TP-422-5726) Avail: CASI HC A03

Researchers in the Biodiesel/Aquatic Species Project focus on the use of microalgae as a feedstock for producing renewable, high-energy liquid fuels. The program's basic premise is that microalgae, which have been called the most productive biochemical factories in the world, can produce up to 30 times more oil per unit of growth area than land plants. It is estimated that 150 to 400 barrels of oil per acre per year (0.06 to 0.16 million liters/hectar) could be produced with microalgal oil technology. Initial commercialization of this technology is envisioned for the desert Southwest because this area provides high solar radiation and offers flat land that has few competing uses (hence low land costs). Similarly, there are large saline aquifers with few competing uses in the region. This water source could provide a suitable, low-cost medium for the growth of many microalgae. The primary area of research during FY 1993 was the effort to genetically improve microalgae in order to control the timing and magnitude of lipid accumulation. Increased lipid content will have a direct effect on fuel price, and the control of lipid content is a major project goal. The paper describes progress on the following: culture collection; molecular biology of lipid biosynthesis; microalgal transformation; and environmental, safety, and health and quality assurance. DOE

XCHEM-1D: A HEAT TRANSFER/CHEMICAL KINETICS COMPUTER PROGRAM FOR MULTILAYERED REACTIVE MATERIALS
R. J. Gross, M. R. Baer, and M. L. Hobbs Oct. 1993 61 p
(Contract DE-AC04-94AL-85000)
(DE94-005072; SAND-93-1603) Avail: CASI HC A04/MF A01

An eXplosive CHEMical kinetics code, XCHEM, was developed to solve the reactive diffusion equations associated with the thermal ignition of energetic materials. This method-of-lines code uses stiff numerical methods and adaptive meshing to resolve relevant combustion physics. Solution accuracy is maintained between multilayered materials consisting of blends of reactive components and/or inert materials. Phase change and variable properties are included in one-dimensional slab, cylindrical, and spherical geometries. Temperature-dependent thermal properties were incorporated and the modification of thermal conductivities to include decomposition effects are estimated using solid/gas volume fractions determined by species fractions. Gas transport properties, including high pressure corrections, were also included. Time varying temperature, heat flux, convective and thermal radiation boundary conditions, and layer to layer contact resistances were also implemented. DOE

THEORETICAL STUDIES OF SOLID-FLUID PHASE EQUILIBRIA
P. A. Monson Jun. 1993 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG02-90ER-14150)
(DE94-006406; DOE/ER-14150/3) Avail: CASI HC A03

Work focused in two directions: understanding the role of anisotropic molecular interactions such as those arising from molecular shape on solid-fluid equilibria and developing a theoretical approach to solid mixtures. A study of the phase diagrams for hard dumbbells (hard sphere dimers), focused especially on the solid-fluid equilibria, was completed; it produced insights into how molecular shape determines the stable crystal structure and solid-fluid equilibria. Results were used to test theoretical predictions from density functional theories and from the cell theory, which were successfully extended to such systems. Results for hard dumbbells provided reference system data for a generalized van der Waals theory of solid-fluid equilibria of nonspherical molecules. This theory provides a basis for understanding trends in experimental solid-fluid equilibrium data, such as reduced triple point temperatures for different substances. A simple extension of this approach to systems with quadrupolar interactions provides a plausible explanation for some features of the phase diagram of CO2 such as its high triple point temperature and large density increase on freezing. The cell theory was extended to mixtures in the solid state. Key development was the incorporation of cell composition fluctuations into the theory. Comparisons with Monte Carlo simulation results for solid-fluid equilibria in hard sphere mixtures show that this theory is the most quantitatively accurate one available and is readily extended to attractive interactions without using a mean field approximation for composition dependence of such interactions. DOE

N94-30761 Midwest Research Inst., Golden, CO.
PROCEEDINGS OF THE LOW COST MATERIALS OF CONSTRUCTION FOR BIOLOGICAL PROCESSES WORKSHOP
13 May 1993 233 p Workshop held in Colorado Springs, CO, 13 May 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-83CH-10093)
(DE94-000218; NREL/CP-420-6032; CONF-9305310) Avail: CASI HC A11

The workshop was held, in May 1993, in conjunction with the 15th Symposium on Biotechnology for Fuels and Chemicals. The purpose of this workshop was to present information on the biomass to ethanol process in the context of materials selection and through presentation and discussion identify promising avenues for future research. Six technical presentations were grouped into two sessions: process assessment and technology assessment. In the process assessment session, the group felt that the pretreatment area would require the most extensive materials research due the complex chemical, physical, and thermal environment. Discussion centered around the possibility of metals being leached into the process stream and their effect on the fermentation mechanics. Linings were a strong option for pretreatment assuming the economics were favorable. Fermentation was considered an important area for research also, due to the unique complex of compounds and dual phases present. Erosion in feedstock handling equipment was identified as a minor concern. In the technology assessment session, methodologies in corrosion analysis were presented in addition to an overview of current coatings/linings technology. Widely practiced testing strategies, including ASTM methods, as well as novel procedures for micro-analysis of corrosion were discussed. Various coatings and linings, including polymers and ceramics, were introduced. The prevailing recommendations for testing included keeping the testing simple until the problem warranted a more detailed approach and developing standardized testing procedures to ensure the data was reproducible and applicable. The need to evaluate currently available materials such as coatings/linings, carbon/stainless steels, or fiberglass reinforced plastic was emphasized. It was agreed that economic evaluation of each material candidate must be an integral part of any research plan. DOE

FUEL CYCLE EVALUATIONS OF BIOMASS-ETHANOL AND REFORMULATED GASOLINE
K. S. Tyson Nov. 1993 130 p Prepared in cooperation with Oak Ridge National Lab., TN Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-83CH-10093)
(DE94-000227; NREL/TP-463-4950) Avail: CASI HC A07

The U.S. Department of Energy (DOE) is using the total fuel cycle analysis (TFCA) methodology to evaluate energy choices. The National Energy Strategy (NES) identifies TFCA as a tool to describe and quantify the environmental, social, and economic costs and benefits associated with energy alternatives. A TFCA should quantify inputs and outputs, their impacts on society, and the value of those impacts that occur from each activity involved in producing and using fuels, cradle-to-grave. New fuels and energy technologies can be consistently evaluated and compared using TFCA, providing a sound basis for ranking policy options that expand the fuel choices available to consumers. This study is limited to creating an inventory of inputs and outputs for three transportation fuels: (1) reformulated gasoline (RFG) that meets the standards of the Clean Air Act Amendments of 1990 (CAAA) using methyl tertiary butyl ether (MTBE); (2) gasohol (E10), a mixture of 10% ethanol made from municipal solid waste (MSW) and 90% gasoline; and (3) E95, a mixture of 5% gasoline and 95% ethanol made from energy crops such as grasses and trees. The ethanol referred to in this study is produced from lignocellulosic material--trees, grass, and organic wastes--called biomass. The biomass is converted to ethanol using an experimental technology described in more detail later. Corn-ethanol is not discussed in this report. This study is limited to estimating an inventory of inputs and outputs for each fuel cycle, similar to a mass balance study, for several reasons: (1) to manage the size of the project; (2) to provide the data required for others to conduct site-specific impact analysis on a case-by-case basis; (3) to reduce data requirements associated with projecting future environmental baselines and other variables that require an internally consistent scenario. ASSESSMENT OF COSTS AND BENEFITS OF FLEXIBLE AND ALTERNATIVE FUEL USE IN THE US TRANSPORTATION SECTOR
Dec. 1993 40 p
(DE94-006100; DOE/PO-0009) Avail: CASI HC A03/MF A01

As part of the alternative fuels assessment, the Department of Energy

(DOE) is studying the use of derivatives of natural gas, including compressed natural gas and methanol, as alternative transportation fuels. A critical part of this effort is determining potential sources of natural gas and the economics of those sources. This report extends previous analyses to include Alaskan North Slope natural gas that either is not being produced or is being reinjected. The report includes the following: a description of discovered and potential (undiscovered) quantities of natural gas on the Alaskan North Slope, a discussion of proposed alternative uses for Alaskan North Slope natural gas, and a comparison of the economics of the proposed alternative uses for Alaskan North Slope natural gas. The purpose is to illustrate the costs of transporting Alaskan North Slope gas to markets in the lower 48 states as pipeline gas, liquefied natural gas (LNG), or methanol. The information is supplied in sufficient detail to allow incorporation of relevant economic relationships (for example, wellhead gas prices and transportation costs) into the alternative fuels trade model, the analytical framework DOE is using to evaluate various policy options. MICROGRAVITY SCIENCE AND APPLICATIONS. PROGRAM TASKS AND BIBLIOGRAPHY FOR FY 1993
Washington Mar. 1994 580 p
(NASA-TM-4569; NAS 1.15:4569) Avail: CASI HC A25/MF A06

An annual report published by the Microgravity Science and Applications Division (MSAD) of NASA is presented. It represents a compilation of the Division's currently-funded ground, flight and Advanced Technology Development tasks. An overview and progress report for these tasks, including progress reports by principal investigators selected from the academic, industry and government communities, are provided. The document includes a listing of new bibliographic data provided by the principal investigators to reflect the dissemination of research data during FY 1993 via publications and presentations. The document also includes division research metrics and an index of the funded investigators. The document contains three sections and three appendices: Section 1 includes an introduction and metrics data, Section 2 is a compilation of the task reports in an order representative of its ground, flight or ATD status and the science discipline it represents, and Section 3 is the bibliography. The three appendices, in the order of presentation, are: Appendix A - a microgravity science acronym list, Appendix B - a list of guest investigators associated with a biotechnology task, and Appendix C - an index of the currently funded principal investigators. FLUID AND TRANSPORTATION PHENOMENA UNDER MICROGRAVITY [BISHO JURYOKUKA NI OKERU RYUTAI YUSO GENSHO]
Yasunori Miyata *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 1-19 In JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

Fluid physics under microgravity has been getting much attention because research is possible free from precipitation or natural convection. In order to effectively utilize of this environment, phenomena specific to microgravity must be studied in view of fluid dynamics. Basic research on fluid dynamics in floating zones under microgravity focused on the fluid stability against rotation or vibration and Marangoni convection generated at temperature differences. The size of stable liquid cylinders is determined to minimize the whole liquid energy. Experiments are done on Marangoni convections in rectangular (or cylindrical) vessels in relation to temperature, solute density, minimum surface tension, and chemical waves. Convection effects and contribution on transportation were also studied. Investigation

was also made on utilization of bubbles and liquid drops to transportation, dynamics of vibrating and rotating liquid drops, and quantization of physical constants. Overall, many experiments are being done about cylindrical stability, Marangoni convections, and liquid drop dynamics under microgravity, but there are several inconveniences and problems yet to be solved.

COMBUSTION STUDIES UNDER MICROGRAVITY [BISHO JURYOKUKA NI OKERU NENSHO KENKYU]
Michikata Kono *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 21-42 In JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

Basically, research was made in the following themes: (1) effects of natural convection, atmospheric pressure and oxygen concentration on combustion of liquid drops; (2) evaporation of fuel liquid drops under hot, high pressure environment; (3) combustion of multi-component fuel liquid drops; (4) self-ignition of fuel liquid drops at high temperature under high pressure; and (5) heat ignition of gas mixture and heat catalysis. The following were found: (1) combustion time was strongly affected by natural convection under normal gravity; (2) natural convection greatly affected evaporation under normal gravity, whereas natural convection was not observed and steam accumulates around liquid drops under microgravity; (3) fuel liquid drops of two components showed three combustion stages under high pressure and microgravity. The critical diameter of liquid drops greatly depended on the initial concentration with higher hexadecane concentration; (4) two-step ignition accompanying cool ignition was observed under low pressure, and ignition time was influenced by natural convection; and (5) under normal gravity, heat was taken away by natural convection, delaying ignition. This effect was more evident if the ignition delay was in large areas. Author (NASDA)

GLASS STUDIES UNDER MICROGRAVITY [BISHO JURYOKU KANKYO O RIYO SHITA GARASU NO KENKYU]
Masaki Makihara *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 43-60 In JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

Floating fusion techniques are important for glass manufacture, and furnaces employing these techniques include sound wave floating furnaces, gas stream sound wave floating furnaces, electromagnetic floating furnaces, electrostatic floating furnaces, and gas film floating furnaces. Glasses generated in microgravity were more uniform, and more tendency for glassification was noted due to vessel-free dissolution. The index of refraction has smaller distribution than that in microgravity. The initial, main objectives of glass studies in microgravity were to: (1) produce glasses with compositions impossible to produce in normal gravity; (2) produce fusing, highly-purified glasses with no vessels; (3) produce hollow glasses to be used for fuel vessels in nuclear reaction experiments; and (4) produce new types of glasses. Although some of them were experimented during Space Shuttle missions, quite a few were discontinued due to lack of equipment or other reasons. There is an opinion to use the sol/gel method to cope with this problem. Another opinion is to employ microgravity environment in glass development and technologies, such as optical fibers with little loss and new glasses for lasers. Author (NASDA)

FABRICATION OF ELECTRONIC MATERIALS IN SPACE [UCHU NI OKERU DENSHI ZAIRYO NO SOSEI]
Yoshihiro Hamakawa *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 61-92 In JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

From a standpoint of new material fabrication, space environment provides five unique characteristics: microgravity, super-high vacuum, abundant solar energy and cosmic rays, good visibility, and vast space. Focusing on the utilization and problems of super-high vacuum environment, the following are phenomena not found on the earth: (1) a phenomenon called 'wake' occurs; (2) metals constantly evaporate from their surfaces, and the evaporation ratio depends on the temperature of the super-high vacuum; (3) metals may adhere each other due to cool deposition; (4) heat is conducted mainly by radiation due to lack of convection in space; (5) discharge is subject to occur; (6) plasma space is generated and potential differences may affect experiments such as electrophoresis; (7) radiation causes some problems such as solar flare being generated, IC's are damaged by radiation, and material may deteriorate by ultraviolet rays; and (8) materials of different specific gravities can be mixed in microgravity. Recently, a new trend is forecasted in view of a technological evolution from the bulk crystalline age to the multilayered thin film age. Possible fabrication and processing for new electronic materials include fabrication of polynary chemical bulk semiconductors and large area thin-film semiconductors as well as oxygen-free vacuum processing. Electronic properties of amorphous semiconductors proved to be far superior to those in normal gravity. Author (NASDA)

PROTEIN CRYSTAL GROWTH IN MICROGRAVITY [BISHO JURYOKUKA NI OKERU TANPAKUSHITSU KESSHO SEICHO]
Mitsuo Ataka *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 93-114 In ENGLISH and JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

The crystals generated in space showed approximately 25 percent improvement at the space experiments of protein crystal growth from the USSR's MIR missions. For Space Shuttles, experiments on protein crystal growth were done on 16 missions. Out of 80 types of protein tested in total, 15 showed results clearly benefiting from the microgravity environment. At the experiments conducted in the Swedish rocket, Maser, both types of protein tested showed larger crystals than their earth-grown counterparts. The high resolution obtained was significant enough to perform X-ray structural analysis, and side chains of amino acid revealed to have two types of conformations. Structural analysis with higher resolution was attained by crystals grown in microgravity. At Stanford University, equipment was developed to control nuclear generation during protein crystal growth as well as to control subsequent growth stages independent of nuclear generation by utilizing partial temperature changes. In Wisconsin, a new protein crystallization method was suggested in which water is selectively removed from protein solution, using reverse permeable films.

CELL CULTURE IN SPACE [UCHU NI OKERU SAIBO BAIYO]
Atsushige Sato *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 115-130 In JAPANESE (For primary document see N94-28938 08-29)
Avail: CASI HC A03/MF A02

Cell culture is used as a substitute for experiments using animals. Also, cultured cells of animals and plants compose physiological-activation materials useful for medicines, and mass cell culture has been utilized for production of such materials. Cell culture is roughly classified into two types: single-layered culture and floating culture. The former is used for cells with substrate dependency and the latter with no substrate dependency. According to the reports from Skylab Three experiments, multiplication and doubling time of cultured cells were almost the same in space and on the earth. Space experiments conducted by the USSR stated that no changes were noted in shapes, physiological activation or multiplication of cultured cells, but the cells were slightly larger and the division index was higher in space. The production of interferon alpha during flight showed increase by four to eight times compared to the earth counterparts. In summary, cell culture will definitely play an important role as a means to biotechnology as well as animal experiments' substitute and analytical means of physiological mechanism. However, there are things to consider such as secondary effects related to culture environment changes and complex reactions from various factors. The research so far is only in the exploration stage, and it should develop into those of a more mature level.

COSMIC ENERGY EQUIPMENT [UCHU KIKI NO ENERUGI SOCHI]

Kazuyuki Enami *In* Japan Space Utilization Promotion Center, Overview of Space Environment Utilization Science Mar. 1993 p 131-149 In JAPANESE (For primary document see N94-28938 08-29)

Avail: CASI HC A03/MF A01

Cosmic energy equipment has three fundamental factors: primary energy sources, conversion equipment of primary energy to electric energy, and unused energy dumping equipment. The primary energy sources are classified into internal sources which are brought in from the earth, and outer sources such as solar energy and high-frequency, optical-ranged convertible energy. Internal sources are either chemical energy sources (e.g. storage batteries, buffer batteries, fuel batteries, electro-chemical power generators), nuclear energy sources (e.g. isotopes, atomic power generators, nuclear reactors) or electromagnetic energy. Solar batteries, utilizing solar energy, are the basic power supply to near-earth orbits, orbiting stations and automatic cosmic equipment. Isotope energy equipment is used when the efficiency of solar batteries are low. Nuclear energy equipment has an advantage of capabilities to function regardless of orbit positions, time of the day, or distance from the sun. Equipment to convert the primary energy to electric energy includes direct energy convertors and mechanical convertors. Both cooling and radiation devices are quite significant for unused energy dumping equipment, because heat can be expelled only by radiation. Author (NASDA)

PLASMA HEATING FOR CONTAINERLESS AND MICROGRAVITY MATERIALS PROCESSING Patent Application

Emily W. Leung, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and Kin F. Man, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 15 Nov. 1993 15 p (Contract NAS7-918)

(NASA-Case-NPO-18819-1-CU; NAS 1.71:NPO-18819-1-CU; US-Patent-Appl-SN-153933) Avail: CASI HC A03/MF A01

A method for plasma heating of levitated samples to be used in containerless microgravity processing is disclosed. A sample is levitated by electrostatic, electromagnetic, aerodynamic, or acoustic systems, as is appropriate for the physical properties of the particular sample. The sample is heated by a plasma torch at atmospheric pressure. A ground plate is provided to help direct the plasma towards the sample. In addition, Helmholtz coils are provided to produce a magnetic field that can be used to spiral the plasma around the sample. The plasma heating system is oriented such that it does not interfere with the levitation system. NASA

MICROGRAVITY COMPATIBLE DRIVE SYSTEM-RIDER. NEW TECHNOLOGIES Technical Note No. 1

H. P. Hildre and T. K. Lien 16 Jun. 1993 57 p Sponsored by European Space Research Organization, Noordwikj, Netherlands

(PB94-138583; STF20-A93105) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report describes the results of a theoretical investigation and analysis of the behavior of reduction gears and linear transmission systems for micro-gravity compatible drive systems. Specific investigations in the area of ultra-low mechanical disturbances are described. The laboratory tests show that the drive system generates unacceptable periodic disturbances. The extreme micro-gravity performance requirements are such that the Traction Reducer becomes an interesting alternative. This alternative will be analyzed and a preliminary design will be presented. LASER BEAM WELDING OF AISI 316 STAINLESS STEEL IN MICROGRAVITY ENVIRONMENT: EXPERIMENTS ABOARD A KC-135 FLIGHT M.S. Thesis

Guoqing Wang Aug. 1993 96 p

(ISBN-0-315-86095-2; CTN-94-61179) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Low power (70-watt) continuous wave CO2 laser welding under microgravity conditions was performed during a KC-135 parabolic flight. The welding experiments were conducted on thin stainless steel (American Iron and Steel Institute 316) strips. The welding parameters were first optimized in ground-based tests and then continuous welding was done during the periods of changing gravity level aboard the KC-135. The weld microstructural characteristics were examined using optical and scanning electron microscopy. During the absence of gravity, wider weld width and deeper weld penetration were found to occur. The weld was characterized by dispersed entrapped slag, porosity, and suspended weld particles, which may lead to a weak joint in real space welding. Author (CISTI)

CONTROL SYSTEM DESIGN FOR A AND R SUPPORTED MICROGRAVITY EXPERIMENTS: AN EXPERIMENT PAYLOAD CONTROL DEVELOPMENT

P. Dieleman 8 Jul. 1992 20 p Presented at the 43rd International Astronautical Federation World Space Congress, Washington, DC, 28 Aug. - 5 Sep. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-B179107; NLR-TP-92327-U; IAF-92-0966; ETN-94-95959) Avail: CASI HC A03

The design of control systems for microgravity experiment payloads, to be integrated into the Columbus infrastructure, for which a comprehensive development methodology is mandatory, is considered. A development model allows structured and formalized development procedures for classes of control systems. A Control Development Methodology (CDM) for Automation and Robotics (A and R) systems, has been proposed by ESA. Ideas to modify and expand this CDM towards a method to develop experiment payload control systems are presented. Such a Payload CDM (PCDM) supports the analysis, design and implementation process of an experiment payload control system. The PCDM consists of engineering guidelines in the form of reference models, standard procedures to support design consistency and traceability, and appropriate tools. ESA

SYSTEMATIC SAFETY CONSIDERATION IN PRODUCT DESIGN Ph.D. Thesis

Markku Reunanen 1993 135 p

(ISSN 1235-0621)

(PB94-132354; VTT/PUB-145; ISBN-951-38-4383-1) Copyright Avail: CASI HC A07/MF A02

Product designers face increasing pressure to improve the level of safety in their designs. To a great extent, the pressure exerted by the regulatory authorities, for example, is currently aimed at product designers. The work was done in order to improve the design process from the point of view of safety. An approach was outlined enabling the inclusion of

safety analyses in the design process in a way that would better reflect the current problems and needs imposed on designers. The basic idea of the approach is that safety analyses are applied in each phase of the design process so that the design is considered during its various levels of maturity. In addition to consideration of the product itself, special attention has been paid to the user instructions needed for safe product operation. The approach was tested in four case studies. NTIS

ARTI REFRIGERANT DATABASE
J. M. Calm 28 Nov. 1993 159 p
(Contract DE-FG02-91CE-23810)
(DE94-004906; DOE/CE-23810/22E) Avail: CASI HC A08/MF A02

The Refrigerant Database consolidates and facilitates access to information to assist industry in developing equipment using alternative refrigerants. The underlying purpose is to accelerate phase out of chemical compounds of environmental concern. The database provides bibliographic citations and abstracts for publications that may be useful in research and design of air-conditioning and refrigeration equipment. The complete documents are not included, though some may be added at a later date. The database identifies sources of specific information on R-32, R-123, R-124, R-125, R-134, R134a, R-141b, R-142b, R-143a, R-152a, R-227ea, R-245ca, R-290 (propane), R-717 (ammonia), ethers, and others as well as azeotropic and zeotropic blends of these fluids. It addresses lubricants including alkylbenzene, polyalkylene glycol, polyol ester, and other synthetics as well as mineral oils. It also references documents addressing compatibility of refrigerants and lubricants with metals, plastics, elastomers, motor insulation, and other materials used in refrigerant circuits. Incomplete citations or abstracts are provided for some documents. They are included to accelerate availability of the information and will be completed or replaced in future updates. DOE

ANNUAL SUMMARY OF BASIC RESEARCH THERMOACOUSTIC HEAT TRANSPORT, 1993
Anthony A. Atchley Nov. 1993 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275751; NPS-PH-94-003) Avail: CASI HC A03

This annual report details progress in basic research in thermoacoustic heat transport made during the period October 1, 1992 through September 30, 1993. Our major research efforts in FY 1993 were concentrated in five areas: (1) an analysis of the initial buildup of oscillations in thermoacoustic prime movers; (2) an investigation of stability curves for a thermoacoustic prime mover; (3) initial measurements of the velocity field in thermoacoustic engines using laser Doppler anemometry; (4) measurements of heat exchanger performance in a thermoacoustic prime mover; and (5) a preliminary investigation of heat driven refrigerators. In addition to these areas, FY 1993 research efforts also included a collaborative experiment on traveling wave thermoacoustic effects. A brief review of the motivation behind these studies and a summary of the important results are contained in this technical report. DTIC

THE DEVELOPMENT AND DEMONSTRATION OF THE METRIC ASSESSMENT TOOL M.S. Thesis
Cynthia A. Campbell and Gregory M. Gutterman Sep. 1993 165 p
(AD-A275786; AFIT/GCM/LAS/93S-3) Avail: CASI HC A08/MF A02

This study reflects the development and demonstration of the metric assessment tool. The purpose of the tool was to provide individuals the means to assess metrics and make improvements to the process measurement. The tool was developed using two critical attributes: customer satisfaction and process improvement. Once the tool was developed, a metric assessment process was designed to demonstrate the tool. Two metrics were selected from the Aeronautical Systems Center (ASC) and individuals with a working knowledge of the metric and process were selected for the demonstrations. Using a group support system at Armstrong Laboratory, Wright Patterson AFB, the group was asked to identify behaviors which might be motivated from the metric. Once the behaviors were identified, the group evaluated the behaviors against the critical attributes. From this assessment, behaviors were placed on the metric assessment tool. This tool clearly identified deficient behaviors and how they might distort the process measurement. From this information, the group was asked to generate improvement actions which would serve to eliminate or control deficient behaviors. With the elimination or control of deficient behaviors, the process measurement is improved and the organizational objective is better served. DTIC

ARGON FROST CONTINUOUS CRYOPUMP FOR FUSION APPLICATIONS
C. A. Foster and H. C. McCurdy 1993 5 p Presented at the Symposium on Fusion Engineering, Hyannis, MA, 11-15 Oct. 1993
(Contract DE-FG05-91ER-81236)
(DE94-004478; CONF-931018-74) Avail: CASI HC A01/MF A01

A cryopumping system based on the snail continuous cryopump concept is being developed for fusion applications under a DOE SBIR grant. The primary pump is a liquid helium cooled compound pump designed to continuously pump and fractionate deuterium/tritium and helium. The D/T pumping stage is a 500 mm bore cryocondensation pump with a nominal pumping speed of 45,000 L/s. It will be continuously regenerated by a snail regeneration head every 12 minutes. Continuous regeneration will dramatically reduce the vulnerable tritium inventory in a fusion reactor. Operating at an inlet pressure of 1 millitorr, eight of these pumps could pump the projected D/T flow in the ITER CDA design while reducing the inventory of tritium in the pumping system from 630 to 43 grams. The helium fraction will be pumped in a compound argon frost stage. This stage will also operate continuously with a snail regeneration head. In addition, the argon spray head will be enclosed inside the snail, thereby removing gaseous argon from the process chamber. Since the cryocondensation stage will intercept over 90% of the D/T/H stream, a purified stream from this stage could be directly reinjected into the plasma as gas or pellets, thereby bypassing the isotope separation system and further simplifying the fuel cycle. Experiments were undertaken in phase 1 which demonstrated continuous cryosorption pumping of hydrogen on CO2 and argon frosts. The pumping system and its relevance to fusion reactor pumping will be discussed. DOE

APPLICATION OF HIGH-SPEED MILLING TO THE FINNISH MANUFACTURING INDUSTRY Final Technical Rept
V. Kauppinen, J. Paro, and I. Nieminen 11 Aug. 1993 90 p Prepared for Technical Research Centre of Finland, Espoo
(PB94-135548) Avail: CASI HC A05/MF A01

The aim of the project was to get knowledge of high-speed milling of different materials with commercially available tools and tool materials. In a preliminary project, the machine tool and the materials to be machined were specified in cooperation with Finnish industry. The report is based on the results of a project on high-speed milling which was recently performed in Finland. NTIS

REALIZING THE PRODUCTIVITY POTENTIAL OF EXPEDITIOUS OPERATIONS
J. Holmstroem 1993 86 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-135555; ISBN-951-22-1773-2) Avail: CASI HC A05

This work addresses the question of how to facilitate sustainable improvements in the operational performance of manufacturing firms. Based on an analysis of international industrial statistics it is argued that there exists a significant productivity potential to be gained from operating expeditiously. Through an analysis of the current discourse in Operations Management it is argued that this productivity potential is based on the improved ability of expeditious firms to deal with uncertainty of the current situation. To realize the potential of expeditious operations a firm must be able to bridge the gap between the reality of words and ideas, and action. Through a case study it is demonstrated how integrative operational structures in combination with enhanced decision making capabilities can facilitate a breakthrough improvement in operational performance. The problem to identifying effective actions to improve the operational performance is approached from a systemic perspective utilizing complementary systems approaches. The utility of a concerted application of statistical, dynamic, and human activity systems approaches is tested in

a case study. Based on the experiences of practical application a systemic framework to implement desirable and feasible actions to improve is constructed. The main contribution of this process model is the inclusion of a human activity systems perspective to deal with the complexity of human affairs. NTIS

MANUFACTURING METHODS FOR MACHINING SPRING ENDS PARALLEL AT LOADED LENGTH Patent Application
Patrick Thomas Hinke, inventor (to NASA) (Allied-Signal Corp., Morristown, NJ.), Dwayne M. Benson, inventor (to NASA) (Allied-Signal Corp., Morristown, NJ.), and Donald J. Atkins, inventor (to NASA) (Allied-Signal Corp., Morristown, NJ.) 10 Nov. 1993 9 p
(NASA-Case-MFS-28767-1; NAS 1.71:MFS-28767-1; US-Patent-Appl-SN-149889) Avail: CASI HC A02/MF A01

A first end surface of a coiled compression spring at its relaxed length is machined to a plane transverse to the spring axis. The spring is then placed in a press structure having first and second opposed planar support surfaces, with the machined spring end surface bearing against the first support surface, the unmachined spring end surface bearing against a planar first surface of a lateral force compensation member, and an opposite, generally spherically curved surface of the compensation member bearing against the second press structure support surface. The spring is then compressed generally to its loaded length, and a circumferentially spaced series of marks, lying in a plane parallel to the second press structure support surface, are formed on the spring coil on which the second spring end surface lies. The spring is then removed from the press structure, and the second spring end surface is machined to the mark plane. When the spring is subsequently compressed to its loaded length the precisely parallel relationship between the machined spring end surfaces substantially eliminates undesirable lateral deflection of the spring. ISO OVERVIEW: GENERAL PRESENTATION OF THE SATELLITE, CRYOGENIC ASPECTS [ISO: PRESENTATION GENERALE DU SATELLITE, ASPECTS CRYOGENIQUES]
Bernard Collaudin 1993 35 p In FRENCH
(Rept-932-440-102; ETN-94-95473) Avail: CASI HC A03/MF A01

A description of the Infrared Spaced Observatory (ISO), (whose launch is planned for Sep. 1995), is presented. The results of cryogenic tests and the current development status are also presented. The ISO is build up around a 60 cm telescope, cooled down to about 3K from an open helium gas loop. Helium is stored in a tank of 2250 liters at 1.8 K. It evaporates across a phase separator. It is designed for an autonomy of 18 months in orbit, for astronomical observation. The whole satellite is 5.3 m long, 2.5 m wide, and weighs about 2400 kg, including 310 kg for helium. ESA

A NORMATIVE FRAME OF REFERENCE FOR THE METROLOGY FUNCTION [UN REFERENTIEL NORMATIF POUR LA FONCTION METROLOGIE]
Pierre Barbier 1993 5 p In FRENCH
(Rept-932-430-102; ETN-94-95460) Avail: CASI HC A01/MF A01

Metrology is discussed and reasons for the necessity of it being exact, its original appearance in the legal domain, its development up until the use of digital techniques, and existing metrological documentation, are discussed. Exact measurements are necessary since the security of individuals or installations depends on the results of such operations. The incertitude of a measurement is determined through comparisons to standards. The metrological documentation includes information on the metrological obligations of certain industries, and means of assuring quality measurements. This documentation contains the norms supplied by a normative reference frame which serves as an information base to facilitate the installation of metrological functions in industries. ESA

Fundamental and practical material to conceive, design, and qualify ventilation systems is presented. The indoor air quality and the thermal environment in ventilated or air conditioned spaces are considered, and information on design rules is identified. The principles and criteria of ventilation systems are discussed. Natural and mechanical ventilation and contaminant control methods are covered. Different empirical flow calculations for steady state and time dependent contaminant generation and air flow rate situations are presented. Their application to sizing of air diffusers, local exhausts, filters and air curtains are illustrated in the cases of laboratory fume and biological safety hoods, grinding booths and spray painting rooms. The theory and use of age distribution and N-zone models are described. Design methodology and technology in the field of industrial ventilation are emphasized. For individual titles, see N94-29599 through N94-29612.

INTRODUCTION TO THE DESIGN OF VENTILATION SYSTEMS
G. Aubertin *In* VKI, Advanced Design of Ventilation Systems 1993 56 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A04/MF A03

The motivations for the installation of a ventilation system are considered: to protect the material or products manufactured at a given site; to eliminate the risk of explosion or dangerous gases or dusts; to reduce the level of pollution and create a healthy atmosphere; and to create comfortable working atmospheres. Additionally, the methods used in their design are described. The methods are all based on the same type of approach and are broken down into three groups which correspond to an empirical, an integral, and a local approach. The empirical approach deals with complex flows with poor or medium accuracy. The local approach deals with the problem of limited range of complexity but with more accuracy and generality. Data available for specific flow configurations such as exhaust devices, jets, and plumes, which to be used for an empirical approach, are given. The integral approach consists of examining a finite volume element of

fluid and integrating the conservation equations over the entire volume. The efficiency of these systems is considered. The local or differential approach consists of determining the characteristics of a fluid at every point in the flow structure. Both viscous and inviscid fluids are considered.

HUMAN REQUIREMENTS TO THE INDOOR AIR QUALITY AND THE THERMAL ENVIRONMENT
P. Ole Fanger *In* VKI, Advanced Design of Ventilation Systems 1993 11 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A03/MF A03

Perceived air quality, general thermal sensation of the occupants and risk of draft, aspects which human comfort in a space depends upon, are reviewed separately based on European Guidelines for Ventilation Requirements in Buildings and on a modified ISO (International Standards Organization) standard 7730 on thermal comfort. The perceived air quality is expressed in decipol or percentage of dissatisfied occupants. The general thermal sensation is expressed by the PMV/PPD indices. The perception of draft is expressed by the model of draft risk. Indoor air quality is mediocre and causes complaints in many buildings. The reason for this is often hidden pollution sources in the building, hitherto ignored in previous ventilation standards. To determine the required ventilation, a method is used in the European Guidelines. The new Guidelines acknowledge all pollution sources in the building, expressed in olfs. The method is based on the desired air quality in the space, the available quality of the outdoor air, the ventilation effectiveness and on the total pollution load in the space. The model of draft risk predicts the percentage of occupants feeling draft as a function of the mean air velocity, the turbulence intensity and the air temperature.

VENTILATION SYSTEMS
L. Olander *In* VKI, Advanced Design of Ventilation Systems 1993 42 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A03/MF A03

Two different types of ventilation systems and their components are addressed: general ventilation and local or process ventilation. Calculation of the flow rates used in the different systems is addressed. The many different types of flow calculations, how they are used, and some of the computer programs that could be used for these calculations are described. Some calculations start with assumptions regarding air flow rates in rooms and locals. The flow rates can be chosen from rule of thumb or regulations or standards. Thereafter the designer calculates necessary heat and cooling loads, pressure drops, fan effect, etc. The other type of calculation is not very common. By using demands on concentrations, temperatures or air velocities the flow rates are calculated. These calculations include contaminant source generation rates, use of models (physical and theoretical), and computational fluid dynamics. The latter are focused upon.

THEORY OF AGE DISTRIBUTION
Eimund Skaaret *In* VKI, Advanced Design of Ventilation Systems 1993 22 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A03/MF A03

The analysis of the age distribution of ventilation air and contaminants is considered with regard to the characterization of the ventilation process. The age distribution functions can be determined using tracer gas or in some cases directly from measurement of the concentration of the actual contaminants. It is important to have in mind that the ventilation air and the contaminants represent different 'populations' and so has to be treated separately. Every air molecule, a member of the 'population' entering the room, spends a certain time there, partly caused by the volume of the space and partly caused by the flow pattern. The residence time varies from molecule to molecule. There is, in other words, a certain characteristic age distribution of the molecules and a characteristic average residence time for the total 'population'. The same can be said about the contaminant molecules.

Copyright Avail: CASI HC A03/MF A03

Industrial ventilation design methodology, using computers and using fluid dynamic models, is considered. It is noted that the design of a ventilation system must be incorporated into the plant design and layout at the earliest conceptual stage of the project. A checklist of activities concerning the methodology for the design of a ventilation system for a new facility is given. A flow diagram of the computer ventilation model shows a typical input, the initialization and iteration loop, and the output. The application of the fluid dynamic modeling techniques include external and internal flow fields, and individual sources of heat and contaminants. Major activities for a ventilation field test program are also addressed.

The components associated with the costs of the purchase of pollution control equipment are discussed. These include the capital cost to purchase the equipment and installation, and the costs incurred to operate the control device on an annual basis. Although the capital costs can represent a significant outlay of money, typically these costs are spread out over the life of the equipment. In general, this amortized cost is combined with the operating cost and is referred to as an 'annualized cost'. The annualized cost is a commonly used indicator to demonstrate the actual year to year cost that the equipment and operation will represent. Values and methods used to estimate costs, typical cost indicators, and sources of computerized costing models are presented. A comparison of the capital cost expenditure required for a model case (a cement kiln operation), using three control device alternatives is made.

COMPUTATIONAL FLUID DYNAMICS IN VENTILATION. 1: THEORY AND ONE-DIMENSIONAL TEST CASE
Peter V. Nielsen *In* VKI, Advanced Design of Ventilation Systems 1993 30 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A03/MF A03

The important role that the development of computer power has had on the design of ventilation systems is considered. This development has lead to decreasing costs and computational time of Computational Fluid Dynamic (CFD) calculations. CFD is an important tool for the prediction of flow in ventilated spaces and there are research areas where people from the indoor environmental technology should, at least, make a major contribution to the further development. The aim of this lecture is to make people who are involved in indoor environmental technology familiar with a number af statement principles and abbreviations. A basic knowledge of CFD which makes it possible to discuss details of the different commercial programs, to read papers on CFD and to start the process of modifying a standard program, is given. The lecture is based on a single (very simple) example, which can be handled by a desk calculator, a pencil and a piece of paper. This should hopefully make the understanding easy. The example takes into account the following: differential equation for one dimensional

flow; difference equation based on Taylor series formulation; discretization equation based on the control volume method; different schemes for the convection and diffusion terms; iterative solution of the discretization equation. ESA

COMPUTATIONAL FLUID DYNAMICS IN VENTILATION: PRACTICAL APPROACH
J. R. Fontaine *In* VKI, Advanced Design of Ventilation Systems 1993 57 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A04/MF A03

The potential of computation fluid dynamics (CFD) for conceiving ventilation systems is shown through the simulation of five practical cases. The following examples are considered: capture of pollutants on a surface treating tank equipped with a unilateral suction slot in the presence of a disturbing air draft opposed to suction; dispersion of solid aerosols inside fume cupboards; performances comparison of two general ventilation systems in a silkscreen printing workshop; ventilation of a large open painting area; and oil fog removal inside a mechanical engineering workshop. Whereas the two first problems are analyzed through two dimensional numerical simulations, the three other cases require three dimensional modeling. For the surface treating tank case, numerical results are compared to laboratory experiment data. All simulations are carried out using EOL, a CFD software specially devised to deal with air quality problems in industrial ventilated premises. It contains many analysis tools to interpret the results in terms familiar to the industrial hygienist. Much experimental work has been engaged to validate the predictions of EOL for ventilation flows. ESA

FINITE ELEMENT METHOD FOR NUMERICAL SIMULATION OF TURBULENT FLOWS. THE N3S CODE
T. Bidot *In* VKI, Advanced Design of Ventilation Systems 1993 40 p (For primary document see N94-29598 08-31)
Copyright Avail: CASI HC A03/MF A03

The N3S thermal hydraulic calculation code which can be fitted to all encountered configurations is considered. It uses the finite element method and so allows local mesh refinements. The aim is to solve the equations of thermal hydraulics, namely Navier-Stokes equations coupled to energy equation in order to take into account thermal convection phenomena, for Reynolds numbers which can vary from several tens to several millions. The constraints which were defined for this code are linked to the industrial environment for which it was developed. It must be able to solve problems of industrial interest with realistic computation times on supercomputers and workstations. The N3S code is used for many industrial applications such as confined flows, thermal hydraulics, turbomachinery, and external flows. The range of application is shown. N3S, with the advantage of tetrahedron for complex three dimensional geometries modeling, expands in the direction of adaptative meshes and moving boundaries, and includes more and more complex physics of fluids. Shigeru Kawamata *In its* Bulletin of National Research Institute of

Fisheries Engineering, No. 13 5 Mar. 1992 p 1-9 In JAPANESE (For primary document see N94-29701 08-31)
Avail: CASI HC A02/MF A02

A simple method of measuring average water velocity was invented for the field survey of water motion affecting benthic organisms. The method uses a vertical thin pipe, an upper chamber filled up with the neutrally buoyant solution of a substance, and a lower chamber packed with porous media to take in ambient water with little variation of water pressure. When this device is set on the flow bed, the solution in the upper chamber is diluted because the solution is pulled out of the pipe by the moving ambient water while the fresh ambient water comes through the lower chamber. An obtained formula of determining the average water velocity during a measurement needs only to measure the initial and last concentrations of the solute in the upper chamber. Furthermore, experiments using models of this device were conducted to prove the feasibility of this idea. It was shown that the method would be practicable but needed some more improvements, especially enhancement of mixing water in the upper chamber. Author (NASDA)

DEVELOPMENT OF THE BREAKWATER WITH SUBMERGED MOUND FOR INTERCHANGING SEA WATER [KAISUI DONYU O MOKUTEKI TO SHITA SENTEITSUKI ANAAKI BOHATEI NO KAIHATSU]

Masaaki Yamamoto, Masamitsu Nakaizumi, Motohumi Manabe, and Akihiko Moriguchi *In its* Bulletin of National Research Institute of Fisheries Engineering, No. 13 5 Mar. 1992 p 11-30 In JAPANESE Sponsored by Fisheries Agency, Tokyo, Japan (For primary document see N94-29701 08-31)
Avail: CASI HC A03/MF A02

Recently it has been necessary to purify mooring basin water in fishing ports for a new utilization, such as stock of live fishes or short term breeding. A new method for interchanging sea water was proposed in which fresh sea water is driven into the port by wave energy, raising mean water level through the wave breaking process over a submerged mound. A hydraulic model test was executed to prove this method to be useful for the interchanging. Results present an appropriate profile and plane configuration. Author (NASDA)

THE UNDRAINED SHEAR STRENGTH CHARACTERISTICS OF UNDISTURBED SOIL FROM FISHING PORT AREAS [GYOKO CHIKU NO SANPURINGUDO NO HI HAISUI KYODO TOKUSEI] **c46**

Seiki Ohmaki, Nobuyuki Horikoshi, Yukio Tsubota, and Ryutaro Yamamoto *In its* Bulletin of National Research Institute of Fisheries Engineering, No. 13 5 Mar. 1992 p 31-56 In JAPANESE (For primary document see N94-29701 08-31)
Avail: CASI HC A03/MF A02

Three types of K0 consolidated undrained compression, extension and isotropically consolidated undrained compression test were carried out on the undisturbed samples from alluvial soil grounds of various fishing port areas in Japan. In these experiments, the values of one to about twenty times effective overburden pressure were used as the axial consolidation pressure. From these experimental results, it is shown that most of the alluvial cohesive soil grounds exhibit the pseudo-overconsolidation property due to secondary compression or cementation effect. The relative relationship of normalized undrained shear strength among three types of experiments conducted here is shown. Using these experimental results, the method of determining the design shear strength for alluvial grounds with a wide range of coarse grain content is proposed. Author (NASDA)

AN IMPROVEMENT OF THE SLENDER BODY THEORY FOR OSCILLATING SHIPS WITH FINITE FORWARD SPEED [ZENSHIN SOKUDO O YUSURU FUNE NO DOYO MONDAI NI TAISURU SAICHOSEN RIRON NO KAIRYO]

Toshikazu Masuya *In its* Bulletin of National Research Institute of Fisheries Engineering, No. 13 5 Mar. 1992 p 57-80 In JAPANESE (For primary document see N94-29701 08-31)
Avail: CASI HC A03/MF A02

A slender-body theory for ship motions with finite forward speed is presented. This is an improvement of an earlier interpolation theory. The original theory is unsatisfactory due to the following: three dimensional effects are overestimated for symmetric motions and vanish for antisymmetric motions. The original theory was recasted, and this flaw was removed. The theory is developed for oscillating ships with finite forward speed and expanded to steady motion problems. Author (NASDA)

THE FLOW FIELD NEAR THE BODY SURFACE WITH THIN FILAMENTS [KOMITSUDO NO RITSUMO SENI DE OWARETA BUTTAI MAWARI NO NAGAREBA NI KANSURU KENKYU] **c34**

Toshihiko Kawashima, Kumiko Adachi, and Hiroyasu Kato *In its* Bulletin of National Research Institute of Fisheries Engineering, No. 13 5 Mar. 1992 p 81-94 In JAPANESE Prepared in cooperation with National Research Inst. of Aquaculture, Mie, Japan; and Toray Industries, Inc., Shiga, Japan (For primary document see N94-29701 08-31)
Avail: CASI HC A03/MF A02

The hydrodynamic characteristics of a flow-field near a surface that is covered with a special cloth that is vertically woven into many thin filaments are presented. The velocity distribution was measured in order to examine the flow mechanism of the boundary layer on the flat plate with thin filaments. The role that the thin filaments play in increasing the boundary layer is discussed. A new fluid phenomenon, the dead water layer, was discovered. The dead water layer exists on the inside of the boundary layer. The fundamental properties of this layer are indicated. Next, the body surface pressure and flow pattern are examined to analyze the influence of the filaments. This was done by using the cylindrical body with thin filaments and by measuring the change due to thin filaments on the pressure distribution. The separation position and the pressure resistance are pointed out. Additional flow characteristics of bodies combined with thin filaments are discussed. Author (NASDA)

DESIGN OF THE BIOSONAR SIMULATOR FOR DOLPHIN'S CLICKS WAVEFORM REPRODUCTION [IRUKA NO KURIKKUSU MEION NO SAISEI HOSHA SOCHI: BAIOSONA SHIMYURETA NO SHISAKU] **c35**

Ken Ishii, Tomonari Akamatsu, and Yoshimi Hatakeyama *In its* Bulletin of National Research Institute of Fisheries Engineering, No. 13 5 Mar. 1992 p 95-128 In JAPANESE (For primary document see N94-29701 08-31)
Avail: CASI HC A03/MF A02

The emitted clicks of Dall's porpoises consist of a pulse train of burst signals with an ultrasonic carrier frequency. The authors have designed a biosonar simulator to reproduce the waveforms associated with a dolphin's clicks underwater. The total reproduction system consists of a click signal acquisition block, a waveform analysis block, a memory unit, a click simulator, and a underwater, ultrasonic wave transmitter. In operation, data stored in an EPROM (Erasable Programmable Read Only Memory) are read out sequentially by a fast clock and converted to analog output signals. Then an ultrasonic power amplifier reproduces these signals through a transmitter. The click signal replaying block is referred to as the BSS (Biosonar Simulator). This is what simulates the clicks. The details of the BSS are described in this report. A unit waveform is defined. The waveform is divided into a burst period and a waiting period. Clicks are a sequence based on a unit waveform, and digital data are sequentially read out from an EPROM of waveform data. The basic parameters of the BSS are as follows: (1) reading clock, 100 ns to 25.4 microseconds; (2) number of reading clock, 34 to 1024 times; (3) counter clock in a waiting period, 100 ns to 25.4 microseconds; (4) number of counter clock, zero to 16,777,215 times; (5) number of burst/waiting repetition cycle, one to 128 times; and (6) transmission level adjustment by a programmable attenuator, zero to 86.5 dB. These basic functions enable the BSS to replay clicks of Dall's porpoise precisely. Author (NASDA)

Field surveys and laboratory experiments on the Japanese anchovy, Engraulis japonica, were conducted in order to identify mechanisms which promote stock size stability. Field surveys confirmed the relatively long spawning season, the short time interval between spawning episodes (interspawning interval), and the seasonal change in batch fecundity. In laboratory experiments, long photoperiod and water temperature played a leading role as a trigger of gonad maturation and spawning. A reduction in food resulted in the following: (1) a prolongation of interspawning interval; (2) a reduction in a batch fecundity; and (3) a change in egg size when the food ration was below the level required for body maintenance. The number of eggs spawned per female was reduced at high density even when food for the individual was held constant. On the other hand, growth was better than in a low density tank. Seawater was removed from the high density tank and discharged into the low density tank. This reduced the number of eggs spawned per female in the low-density tank. However this did not apply for sea water from a low-density tank and also a high-density tank without mature fish. Therefore, some unknown organic substance may control gonad maturation. THE PLUTO FAST FLYBY MISSION: COMPLETING THE RECONNAISSANCE OF THE SOLAR SYSTEM Abstract Only **c91**
Paul K. Henry *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 13 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

The concept of a fast flyby mission to Pluto has been advanced as a means to complete the reconnaissance of the known solar system. In order to acquire data on the Pluto system at the earliest possible time, and within the professional lifetime of investigators now active in the field, concepts are being developed for relatively small spacecraft in the mass range of 70 Kg to 350 Kg with flight times to Pluto of 7 to 13 years. Necessarily, the science complement on such a mission will be very mass and power limited. The challenge will be to define a spacecraft and an instrument package that will maximize the scientific return within these limitations. Cost, of course, will be a major consideration, and funds for new technology development specific to this mission will not be extensive. Consequently, innovative ways to incorporate elegant simplicity into the designs must be found. In order to facilitate exploration of the Pluto-Charon system, fully integrated science payloads must be developed. Two proposed mission designs involving limited mass and power science payloads have been presented to the Outer Planets Science Working Group (OPSWG). These payload mass allocations range from 5 to 30 kilograms with power allocations as low as 5 watts. The drivers behind these low mass and power allocations are that they enable developing missions to fit within the moderate mission cost profile and allow fast flight times to Pluto (7 to 13 years). The OPSWG has prioritized science goals for this class of reconnaissance mission. Three specific science objectives were identified as the highest priority required for the first Pluto mission. These goals were: (1) study of the neutral atmosphere, (2) geology and morphology, and (3) surface compositional mapping. In order to achieve these science goals within the constraints of low mass, power and cost, it may be necessary to combine the functions of 3 conventional instruments (CCD camera, Ultra-Violet Spectrometer, and Infrared Spectrometer) into one fully integrated payload. Where possible, this payload would share optics, mechanisms, electronics and packaging. Author

MICROMANUFACTURING: RECENT DEVELOPMENTS IN THIS COUNTRY AND ABROAD
Robert O. Warrington, Craig R. Friedrich, Robert X. Gao, and Gang Lin *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 21-28 (For primary document see N94-29767 08-31)
Avail: CASI HC A02/MF A03

This paper has attempted to summarize some recent activities in this country and overseas. The effort in Louisiana is relatively new and growing. The Russian effort is not well coordinated or documented. A conference on Micro Systems Technologies is scheduled for June of 1993 in St. Petersburg, Russia. Serious consideration should be given to developing a strategy to not only participate in this meeting, but also to spend additional time in Russia assessing the technology. MEMS technologies will eventually affect virtually every aspect of our lives and, at least in the near term, mini-devices with micro-components will probably be the economic drivers for the technology. LIGA is a procession sequence which uses x-ray lithography on photoresist layers of several hundred micrometers to produce very high edge acuity photopolymer molds. These plastic molds can be converted to metal molds via electroplating of many different metals and alloys. The end results are high edge acuity metal parts with large structural heights. The LIGA process as originally described by W. Ehrfeld can be extended by adding a surface micromachining phase to produce precision metal parts which can be assembled to form three-dimensional micromechanisms. This process, SLIGA, has been used to fabricate a dynamometer on a chip. The instrument has been fully implemented and will be applied to tribology issues, speed-torque characterization of planar magnetic micromotors and a new family of sensors. Author

This paper gives an overview of micro-guidance and control technologies and in the process previews of the technology/user and systems issues presented in the guidance and control session at the workshop. We first present a discussion of the advantages of using micro-guidance and control components and then detail six micro-guidance and control thrusts that could have a revolutionary impact on space missions and systems. Specific technologies emerging in the micro-guidance and control field will be examined. These technologies fall into two broad categories: micro-attitude determination (inertial and celestial) and micro-actuation, control and sensing. Finally, the scope of the workshop's guidance and control panel are presented. Author

The paper presents advances in two new sensor technologies and a miniaturized associated electronics technology which, when combined, can allow for very significant miniaturization and for the reduction of weight and power consumption in x-ray and gamma-ray spectroscopy systems: (1) Mercuric iodide (HgI2) x-ray technology, which allows for the first time the construction of truly portable, high-energy resolution, non-cryogenic x-ray fluorescence (XRF) elemental analyzer systems, with parameters approaching those of laboratory quality cryogenic instruments; (2) the silicon avalanche photodiode (APD), which is a solid-state light sensitive device with internal amplification, capable of uniquely replacing the vacuum photomultiplier tube in scintillation gamma-ray spectrometer applications, and offering substantial improvements in size, ruggedness, low power operation and energy resolution; and (3) miniaturized (hybridized) low noise, low power amplification and processing electronics, which take full advantage of the favorable properties of these new sensors and allow for the design and fabrication of advanced, highly miniaturized x-ray and gamma-ray spectroscopy systems. The paper also presents experimental results and examples of spectrometric systems currently under construction. The directions for future developments are discussed. Author

BACKSCATTER MOSSBAUER SPECTROMETER (BaMS) FOR EXTRATERRESTRIAL APPLICATIONS **c35**

D. G. Agresti (Alabama Univ., Birmingham.), T. D. Shelfer (Alabama Univ., Birmingham.), M. M. Pimperl (Alabama Univ., Birmingham.), E. L. Wills (Alabama Univ., Birmingham.), M. H. Shen (Alabama Univ., Birmingham.), and R. V. Morris *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 95-97 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

Mossbauer spectroscopy is a nuclear gamma resonance technique particularly well suited to the study of materials that contain iron (Fe-57). It can provide information on the oxidation state of iron as well as the type and proportion of iron-containing mineral species in a sample of interest. Iron Mossbauer spectroscopy (FeMS) has been applied to samples believed to have come from Mars (SNC meteorites) and has been helpful in refining the choice among putative Martian surface materials by suggesting a likely nanophase component of the Martian regolity. FeMS spectrum of a Martial analogue material (Hawaiian palagonite) is shown; it is dominated by ferric-bearing phases and shows evidence of a nanophase component. FeMS has also been applied to lunar materials. It can be used to measure the maturity of lunar surface material and has been proposed as a prospector for lunar ilmenite, an oxygen resource mineral. Several years ago we suggested a backscatter Mossbauer spectrometer (BaMS) for a Mars rover mission. Backscatter design was selected as most appropriate for in-situ application because no sample preparation is required. Since that time, we have continued to develop the BaMS instrument in anticipation that it would eventually find a home on a NASA planetary mission. Gooding proposed BaMS as a geochemistry instrument on MESUR. More recently, an LPI workshop has recommended that BaMS be included in a three-instrument payload on the next (1996?) lunar lander. Avail: CASI HC A03/MF A03

A new approach for fabricating macroscopic (approximately 10x10x10 mm(exp 3)) structures with micron accuracy has been developed. This approach combines the precision of semiconductor processing and fiber optic technologies. A (100) silicon wafer is anisotropically etched to create four orthogonal v-grooves and an aperture on each 10x12 mm die. Precision 308 micron optical fibers are sandwiched between the die to align the v-grooves. The fiber is then anodically bonded to the die above and below it. This procedure is repeated to create thick structures and a stack of 5 or 6 die will be used to create a miniature scanning electron microscope (MSEM). Two die in the structure will have a segmented electrode to deflect the beam and correct for astigmatism. The entire structure is UHV compatible. The performance of an SEM improves as its length is reduced and a sub-cm 2 keV MSEM with a field emission source should have approximately 1 nm resolution. A low voltage high resolution MSEM would be useful for the examination of biological specimens and semiconductors with a minimum of damage. The first MSEM will be tested with existing 6 micron thermionic sources. In the future a micromachined field emission source will be used. The stacking technology presented in this paper can produce an array of MSEMs 1 to 30 mm in length with a 1 mm or larger period. A key question being addressed by this research is the optimum size for a low voltage MSEM which will be determined by the required spatial resolution, field of view, and working distance. DIFFERENTIAL SCANNING CALORIMETRY (DSC) FOR PLANETARY SURFACE EXPLORATION **c35**

James L. Gooding and Douglas W. Ming *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 121-12 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

Differential Scanning Calorimetry (DSC) is the quantitative measurement of the enthalpic response of a material to a systematic change in temperature. In practice, the heat flow into or outward from a sample is measured as the sample is heated or cooled at a carefully controlled rate. DSC superficially resembles, but is not the same as differential thermal analysis (DTA), which is the measurement of temperature differences between a sample and reference material as the pair is heated or cooled. The fundamental properties measured by DSC are enthalpies and temperatures of phase transitions and constant-pressure heat capacities. Depending on instrument design and the nature of the sample, high-quality DSC analyses can be obtained on only a few milligrams of solid materials. DSC requires direct contact with the sample and generally degrades, if not destroys, the sample as a consequence of heating. In laboratory applications, it is common to subject the gaseous effluent from the DSC to analysis by a separate evolved-gas analyzer (EGA). Author

MICRO-SENSORS FOR IN-SITU METEOROLOGICAL MEASUREMENTS **c47**

David Crisp, William J. Kaiser, Thomas R. VanZandt, and James E. Tillman *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 123-124 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

Improved in-situ meteorological measurements are needed for monitoring

the weather and climate of the terrestrial and Martian atmospheres. We have initiated a program to assess the feasibility and utility of micro-sensors for precise in-situ meteorological measurements in these environments. Sensors are being developed for measuring pressure, temperature, wind velocity, humidity, and aerosol amounts. Silicon micro-machining and large scale integration technologies are being used to make sensors that are small, rugged, lightweight, and require very little power. Our long-term goal is to develop very accurate miniaturized sensors that can be incorporated into complete instrument packages or 'micro weather stations,' and deployed on a variety of platforms. If conventional commercially available silicon production techniques can be used to fabricate these sensor packages, it will eventually be possible to mass-produce them at low cost. For studies of the Earth's troposphere and stratosphere, they could be deployed on aircraft, dropsondes, radiosondes, or autonomous surface stations at remote sites. Improved sensor accuracy and reduced sensor cost are the primary challenges for these applications. For studies of the Martian atmosphere, these sensor packages could be incorporated into the small entry probes and surface landers that are being planned for the Mars Environmental SURvey (MESUR) Mission. That decade-long program will deploy a global network of small stations on the Martian surface for monitoring meteorological and geological processes. Low mass, low power, durability, large dynamic range and calibration stability are the principal challenges for this application. Our progress on each of these sensor types is presented. Author

A BROAD-BAND MICROSEISMOMETER FOR PLANETARY OPERATIONS **c35**
W. B. Banerdt, T. VanZandt, W. J. Kaiser, and T. W. Kenny *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 125-126 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

There has recently been renewed interest in the development of instrumentation for making measurements on the surface of Mars. This is due to the Mars Environmental Survey (MESUR) Mission, for which approximately 16 small, long-lived (2-10 years), relatively inexpensive surface stations will be deployed in a planet-wide network. This will allow the investigation of processes (such as seismology and meteorology) which require the simultaneous measurement of phenomena at many widely spaced locations on the surface over a considerable length of time. Due to the large number of vehicles involved, the mass, power, and cost of the payload will be severely constrained. A seismometer has been identified as one of the highest priority instruments in the MESUR straw-man payload. The requirements for an effective seismic experiment on Mars place a number of constraints on any viable sensor design. First, a large number of sensors must be deployed in a long-lived global network in order to be able to locate many events reliably, provide good spatial sampling of the interior, and increase the probability of seismic detection in the event of localized seismicity and/or high attenuation. From a practical standpoint, this means that individual surface stations will necessarily be constrained in terms of cost, mass, and power. Landing and thermal control systems will probably be simple, in order to minimize cost, resulting in large impact accelerations and wide daily and seasonal thermal swings. The level of seismic noise will determine the maximum usable sensitivity for seismometer. Unfortunately, the ambient seismic noise level for Mars is not well known. However lunar seismic noise levels are several orders of magnitude below that of the Earth. Sensitivities on the order of 10(exp -11)g over a bandwidth of .04 to 20 Hz are thought to be necessary to fulfill the science objectives for a seimometer placed on the Martian surface. Silicon micromachined sensor technology offers techniques for the fabrication of monolithic, robust, compact, lower power and mass accelerometers. Conventional micro-machined accelerometers have been developed and are commercially available for high frequency and large acceleration measurements. The new seismometer we are developing incorporates certain principles of conventional silicon micromachined accelerometer technology. However, currently available silicon micromachined sensors offer inadequate sensitivity and bandwidth for the Mars seismometer application. Our implementation of an advanced silicon micromachined seismometer is based on principles recently developed at JPL for high-sensitivity position sensor technology.

IMAGING SPECTROMETRY OF THE EARTH AND OTHER SOLAR SYSTEM BODIES Abstract Only **c35**
Gregg Vane *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 127 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

Imaging spectrometry is a relatively new tool for remote sensing of the Earth and other bodies of the solar system. The technique dates back to the late 1970's and early 1980's. It is a natural extension of the earlier multi-spectral imagers developed for remote sensing that acquire images in a few, usually broad spectral bands. Imaging spectrometers combine aspects of classical spectrometers and imaging systems, making it possible to acquire literally hundreds of images of an object, each image in a separate, narrow spectral band. It is thus possible to perform spectroscopy on a pixel-by-pixel basis with the data acquired with an imaging spectrometer. Two imaging spectrometers have flown in space and several others are planned for future Earth and planetary missions. The French-built Phobos Infrared Spectrometer (ISM) was part of the payload of the Soviet Mars mission in 1988, and the JPL-built Near Infrared Mapping Spectrometer (NIMS) is currently en route to Jupiter aboard the Galileo spacecraft. Several airborne imaging spectrometers have been built in the past decade including the JPL-built Airborne Visible/Infrared Imaging Spectrometer (AVIRIS) which is the only such sensor that covers the full solar reflected portion of the spectrum in narrow, contiguous spectral bands. NASA plans two imaging spectrometers for its Earth Observing System, the Moderate and the High Resolution Imaging Spectrometers (MODIS and HIRIS). A brief overview of the applications of imaging spectrometry to Earth science will be presented to illustrate the value of the tool to remote sensing and indicate the types of measurements that are required. The system design for AVIRS and a planetary imaging spectrometer will be presented to illustrate the engineering considerations and challenges that must be met in building such instruments. Several key sensor technology areas will be discussed in which miniaturization and/or enhanced performance through micromachining and nanofabrication may allow smaller, more robust, and more capable imaging spectrometers to be built in the future. SMART FOCAL-PLANE TECHNOLOGY FOR MICRO-INSTRUMENTS AND MICRO-ROVERS **c63**
Eric R. Fossum *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 129-130 (For primary document see N94-29767 08-31)
Avail: CASI HC A01/MF A03

It is inevitable that micro-instruments and micro-rovers for space exploration will contain one or more focal-plane arrays for imaging, spectroscopy, or navigation. In this paper, we explore the state-of-the-art in focal-plane technology for visible sensors. Also discussed is present research activity in advanced focal-plane technology with particular emphasis on the development of smart sensors. The paper concludes with a discussion of possible future directions for the advancement of the technology.

EVOLUTION OF MINIATURE DETECTORS AND FOCAL PLANE ARRAYS FOR INFRARED SENSORS **c74**
Louis A. Watts *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 131-14 (For primary document see N94-29767 08-31)
Avail: CASI HC A02/MF A03

Sensors that are sensitive in the infrared spectral region have been under continuous development since the WW2 era. A quest for the military advantage of 'seeing in the dark' has pushed thermal imaging technology toward high spatial and temporal resolution for night vision equipment, fire control, search track, and seeker 'homing' guidance sensing devices. Similarly, scientific applications have pushed spectral resolution for chemical analysis, remote sensing of earth resources, and astronomical exploration applications. As a result of these developments, focal plane arrays (FPA) are now available with sufficient sensitivity for both high spatial and narrow bandwidth spectral resolution imaging over large fields of view. Such devices combined with emerging opto-electronic developments in integrated FPA

data processing techniques can yield miniature sensors capable of imaging reflected sunlight in the near IR and emitted thermal energy in the Mid-wave (MWIR) and longwave (LWIR) IR spectral regions. Robotic space sensors equipped with advanced versions of these FPA's will provide high resolution 'pictures' of their surroundings, perform remote analysis of solid, liquid, and gas matter, or selectively look for 'signatures' of specific objects. Evolutionary trends and projections of future low power micro detector FPA developments for day/night operation or use in adverse viewing conditions are presented in the following test. Author (revised)

ADVANCED MICROFABRICATION TECHNOLOGIES FOR MICROSPACECRAFT **c18**

M. Ghezzo, B. Bagepalli, S. Kodiyalam, C. Korham, K. Browall, and Norman Alexander *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 157 (For primary document see N94-29767 08-31)

Avail: CASI HC A01/MF A03

Advanced microfabrication technologies offer the prospect of reducing the weight and size of spacecraft through the use of lighter and stronger materials in conjunction with new mechanical/structural design concepts and design optimization methods. At the same time, electronic components have been scaled down while increasing functional utility. A two-fold benefit is derived for space applications through the use of less expensive components and the lower launch costs associated with lighter components. GE-CRD is actively pursuing research in these key technologies for a wide range of applications including satellites. These key technologies will be reviewed and an update on GE progress will be given. The need to reduce weight and lower cost, while maintaining product quality and reliability are primary drivers in the design of satellites, in general, and microsatellites in particular. For the structural subsystem, these requirements pose a complex design problem unless new mechanical design concepts and computer-aided design optimization methods are employed. Several new concepts, such as battery packs doubling as panel reinforcements and fuel tanks as integral structural members, need to utilized. In addition, new viscoelastic material damping concepts for spacecraft components provide for lighter weight/lower cost designs, while satisfying the structural dynamics requirements. High density interconnect (HDI) technology permits the use of bare IC's on a ceramic substrate with 90 percent active area utilization. A copper/polyimide multilayer structure is the backbone of the technology, which has demonstrated a size/weight reduction of greater than 10x compared to printed circuit board with performance up to the GHz level. HDI modules have exceptional mechanical robustness as evidenced by survival of 180 kg rapid acceleration tests. Microelectromechanical systems (MEMS) are redefining sensors and actuators by miniaturization through micromachining techniques. Sharing many fabrication steps with HDI, we have developed a new technique for surface micromachining of copper/polyimide structures using computer-aided laser patterning. Author (revised)

MICROFABRICATED SILICON BIOSENSORS FOR MICROPHYSIOMETRY **c51**

L. J. Bousse, J. M. Libby, and J. W. Parce *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 163-18 (For primary document see N94-29767 08-31)

(Contract MDA972-92-C-0005)

Avail: CASI HC A03/MF A03

Microphysiometers are biosensor devices that measure the metabolic rate of living cells by detecting the rate of extracellular acidification caused by a small number of cells. The cells are entrapped in a microvolume chamber, whose bottom surface is a silicon sensor chip. In a further miniaturization step, we have recently fabricated multichannel flow-through chips that will allow greater throughput and multiplicity. Microphysiometer technology can be applied to the detection of microorganisms. We describe the sensitive detection of bacteria and yeast. Further applications of microphysiometry to the characterization of microorganisms can be anticipated. Author

TOWARD MILLI-NEWTON ELECTRO- AND MAGNETO-STATIC MICROACTUATORS **c33**

Long-Sheng Fan *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 191-20 (For primary document see N94-29767 08-31)

Avail: CASI HC A03/MF A03

Microtechnologies can potentially push integrated electro- and magnetostatic actuators toward the regime where constant forces in the order of milli-Newton (or torques in the order of micro-Newton meter) can be generated with constant inputs within a volume of 1.0 x 1.0 x 0.02 mm with 'conventional' technology. 'Micro' actuators are, by definition, actuators with dimensions confined within a millimeter cube. Integrated microactuators based on electrostatics typically have force/torque in the order of sub-micro-Newton (sub-nano-Newton meter). These devices are capable of moving small objects at MHz frequencies. On the other hand, suppose we want to move a one cubic millimeter object around with 100 G acceleration; a few milli-Newton force will be required. Thus, milli-Newton microactuators are very desirable for some immediate applications, and it challenges micromechanical researchers to develop new process technologies, designs, and materials toward this goal. MICROMACHINED ELECTRON TUNNELING INFRARED SENSORS **c74**

T. W. Kenny, W. J. Kaiser, J. A. Podosek, H. K. Rockstad, and J. K. Reynolds *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 205-212 (For primary document see N94-29767 08-31)

Avail: CASI HC A02/MF A03

The development of an improved Golay cell is reported. This new sensor is constructed entirely from micromachined silicon components. A silicon oxynitride (SiO(x)N(y)) membrane is deflected by the thermal expansion of a small volume of trapped gas. To detect the motion of the membrane, an electron tunneling transducer is used. This sensor detects electrons which tunnel through the classically forbidden barrier between a tip and a surface; the electron current is exponentially dependent on the separation between the tip and the surface. The sensitivity of tunneling transducers constructed was typically better than 10(exp -3) A/square root of Hz. Through use of the electron tunneling transducer, the scaling laws which have prevented the miniaturization of the Golay cell are avoided. This detector potentially offers low cost fabrication, compatibility with silicon readout electronics, and operation without cooling. Most importantly, this detector may offer better sensitivity than any other uncooled infrared sensor, with the exception of the original Golay cell. Derived from text

MACRO, MINI, MICRO AND NANO (M(SUP 3)N) TECHNOLOGIES FOR THE FUTURE

Craig R. Friedrich, Robert O. Warrington, Robert X. Gao, and Gang Lin *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 213-22 (For primary document see N94-29767 08-31)

Avail: CASI HC A02/MF A03

Microelectromechanical systems (MEMS), micro systems technologies (MST), and micromanufacturing are relatively recent phrases or acronyms that have become synonymous with the design, development, and manufacture of 'micro' devices and systems. Micromanufacturing encompasses MEMS or MST and, in addition, includes all of the processes involved in the production of micro things. Integration of mechanical and electrical components, including built-in computers, can be formed into systems which must be connected to the macroworld. Macro, mini, micro, and nano technologies are all a part of MEMS or micromanufacturing. At this point in the development of the technology, it is becoming apparent that mini systems, with micro components, could very well be the economic drivers of the technology for the foreseeable future. Initial research in the fabrication of microdevices using IC processing technology took place over thirty years ago. Anisotropic etching of silicon was used to produce piezoresistive diaphragms. Since the early 60's, there has been gradual progress in MEMS until the early 1980's when worldwide interest in the technology really started to develop. During this time high aspect ratio

micromachining using x rays was started in Germany. In 1987 the concept of a 'silicon micromechanics foundry' was proposed. Since then the interest in the U.S., Germany, and Japan has increased to the point where hundreds of millions of dollars of research monies are being funneled into the technology (at least in Germany and Japan) and the technology has been classified as critical or as a technology or national importance by the U.S. government. CONTROL OF MICROMACHINED DEFORMABLE MIRRORS **c74**
M. L. Agronin, R. Bartman, F. Y. Hadaegh, W. Kaiser, and P. K. C. Wang *In its* Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 225-246 (For primary document see N94-29767 08-31)
Avail: CASI HC A03/MF A03

A micromachined deformable mirror with pixelated electrostatic actuators is proposed. The paper begins with a physical description of the proposed mirror. Then a mathematical model in the form of a nonlinear partial differential equation describing the mirror surface deformations is derived. This model is used to derive the required voltages for the actuators to achieve a specified static deformation of the mirror surface. This is followed by the derivation of a static nonlinear feedback controller for achieving noninteracting actuation. Then the structure for a complete control system for wavefront correction is proposed. The paper concludes with a discussion of the physical implementation of the proposed control system. Author

Employing recent advances in microfabrication, the Charles Stark Draper Laboratory has developed inertial guidance instruments of very small size and low cost. Microfabrication employs the batch processing techniques of solid state electronics, such as photolithography, diffusion, and etching, to carve mechanical parts. Within a few years, microfabricated gyroscopes should perform in the 10 to 100 deg/h range. Microfabricated accelerometers have demonstrated performance in the 50 to 500 microgravity range. These instruments will result in not only the redesign of conventional military products, but also new applications that could not exist without small, inexpensive sensors and computing. Draper's microfabricated accelerometers and gyroscopes will be described and test results summarized. Associated electronics and control issues will also be addressed. Gimballed, vibrating gyroscopes and force rebalance accelerometers constructed from bulk silicon, polysilicon surface-machined tuning fork gyroscopes, and quartz resonant accelerometers and gyroscopes are examined. Draper is pursuing several types of devices for the following reasons: to address wide ranges of performance, to realize construction in a flat pack, and to lessen the risks associated with emerging technologies. Avail: CASI HC A03/MF A03

Prototypes of a piezo-electric vibratory angular rate transducer (gyroscope) (PVG) have been constructed and evaluated. The construction is on the lines suggested by Burdess. The sensitive element is a cylinder of radially poled piezo-electric ceramic. The cylinder is metallized inside and out, and the outer metallization is divided into eight electrodes. The metallization on the inside is earthed. A phase locked loop, using pairs of the electrodes, causes the cylinder to vibrate in one of its two fundamental, degenerate modes. In the presence of rotation, some of the vibration is coupled into the outer mode. This can be detected, or suppressed with a closed-up technique and provides a measure of rotation rate. The gyroscope provides a number of advantages over rotating mass and optical instruments: low size and mass, lower power consumption, potentially high reliability, potentially good dormancy, low cost and high maximum rate. Micromachined sensors promise significant system advantages to manned space vehicles. Vehicle Health Monitoring (VHM) is a critical need for most future space systems. Micromachined sensors play a significant role in advancing the application of VHM in future space vehicles. This paper addresses the requirements that future VHM systems place on micromachined sensors such as: system integration, performance, size, weight, power, redundancy, reliability and fault tolerance. Current uses of micromachined sensors in commercial, military and space systems are used to document advantages that are gained and lessons learned. Based on these successes, the future use of micromachined sensors in space programs is discussed in terms of future directions and issues that need to be addressed such as how commercial and military sensors can meet future space system requirements. New GN&C (guidance, navigation and control) system capabilities are shown to arise from component innovations that involve the synergistic use of microminiature sensors and actuators, microelectronics, and fiber optics. Micro-GN&C system and component concepts are defined that include micro-actuated adaptive optics, micromachined inertial sensors, fiber-optic data nets and light-power transmission, and VLSI microcomputers. The thesis is advanced that these micro-miniaturization products are capable of having a revolutionary impact on space missions and systems, and that GN&C is the pathfinder micro-technology application that can bring that about. The integration of high quality, single crystal thin film gallium arsenide (GaAs) and indium phosphide (InP) based photonic and electronic materials and devices with host microstructures fabricated from materials such as silicon (Si), glass, and polymers will enable the fabrication of the next generation of micro-opto-mechanical systems (MOMS) and optoelectronic integrated circuits. Thin film semiconductor devices deposited onto arbitrary host substrates and structures create hybrid (more than one material) near-monolithic integrated systems which can be interconnected electrically using standard inexpensive microfabrication techniques such as vacuum

metallization and photolithography. These integrated systems take advantage of the optical and electronic properties of compound semiconductor devices while still using host substrate materials such as silicon, polysilicon, glass and polymers in the microstructures. This type of materials optimization for specific tasks creates higher performance systems than those systems which must use trade-offs in device performance to integrate all of the function in a single material system. The low weight of these thin film devices also makes them attractive for integration with micromechanical devices which may have difficulty supporting and translating the full weight of a standard device. These thin film devices and integrated systems will be attractive for applications, however, only when the development of low cost, high yield fabrication and integration techniques makes their use economically feasible. In this paper, we discuss methods for alignment, selective deposition, and interconnection of thin film epitaxial GaAs and InP based devices onto host substrates and host microstructures. Author

MINIATURE WIDE FIELD-OF-VIEW STAR TRACKERS FOR SPACECRAFT ATTITUDE SENSING AND NAVIGATION **c04**
William McCarty, Eric Curtis, Anthony Hull, and William Morgan *In* JPL, Proceedings of the Workshop on Microtechnologies and Applications to Space Systems 15 Jun. 1993 p 317-32 (For primary document see N94-29767 08-31)
Avail: CASI HC A03/MF A03

Introducing a family of miniature, wide field-of-view star trackers for low cost, high performance spacecraft attitude determination and navigation applications. These devices, derivative of the WFOV Star Tracker Camera developed cooperatively by OCA Applied Optics and the Lawrence Livermore National Laboratory for the Brilliant Pebbles program, offer a suite of options addressing a wide range of spacecraft attitude measurement and control requirements. These sensors employ much wider fields than are customary (ranging between 20 and 60 degrees) to assure enough bright stars for quick and accurate attitude determinations without long integration intervals. The key benefit of this approach are light weight, low power, reduced data processing loads and high information carrier rates for wide ACS bandwidths. Devices described range from the proven OCA/LLNL WFOV Star Tracker Camera (a low-cost, space-qualified star-field imager utilizing the spacecraft's own computer and centroiding and position-finding), to a new autonomous subsystem design featuring dual-redundant cameras and completely self-contained star-field data processing with output quaternion solutions accurate to 100 micro-rad, 3 sigma, for stand-alone applications. The FORTE (Fast On-Orbit Recording of Transient Events) small satellite is scheduled for launch in mid 1995. The mission is to measure and classify VHF (30-300 MHz) electromagnetic pulses, primarily due to lightning, within a high noise environment dominated by continuous wave carriers such as TV and FM stations. The FORTE Event Classifier will use specialized hardware to implement signal processing and neural network algorithms that perform onboard classification of RF transients and carriers. Lightning events will also be characterized with optical data telemetered to the ground. A primary mission science goal is to develop a comprehensive understanding of the correlation between the optical flash and the VHF emissions from lightning. By combining FORTE measurements with ground measurements and/or active transmitters, other science issues can be addressed. Examples include the correlation of global precipitation rates with lightning flash rates and location, the effects of large scale structures within the ionosphere (such as traveling ionospheric disturbances and

horizontal gradients in the total electron content) on the propagation of broad bandwidth RF signals, and various areas of lightning physics. Event classification is a key feature of the FORTE mission. Neural networks are promising candidates for this application. The authors describe the proposed FORTE Event Classifier flight system, which consists of a commercially available digital signal processing board and a custom board, and discuss work on signal processing and neural network algorithms. DATA FUSION AND CORRELATION TECHNIQUES TESTBED DEVELOPMENT AUDIO PROCESSING STUDY
28 Sep. 1990 28 p Submitted for publication
(SKD-1600-73-014; DSIS-94-00150; CTN-94-61126) Avail: CASI HC A03/MF A01

A study was performed as part of the development of the Data Fusion and Correlation Testbed (DFACT) prototype to investigate the audio processing requirements of the DFACT system. The DFACT system was conceived to provide a testbed for design and implementation of software architectures and communications sensor information, and analysis and correlation algorithms, for land electronic warfare. The base system consists of a number of analyst workstations and intercept operator workstations interconnected through Ethernet. A number of computer controlled intercept receivers along with a communications emitter locating system provide data to DFACT for reduction, correlation, and fusion activities. Intercepted messages are transcribed by the intercept operators and stored in a database for further processing by the analysts. The study examines the basic audio processing capabilities required by DFACT both from a functional and processing perspective. Issues related to throughput, storage capacity, and data retrieval are examined, and a suitable system architecture for a DFACT audio processor is described that satisfies all DFACT system audio processing requirements. SPC TOOLBOX: AN INTERACTIVE MATLAB (TM) PACKAGE FOR SIGNAL MODELING, ANALYSIS, AND COMMUNICATIONS
Dennis W. Brown and Monique P. Fargues 15 Oct. 1993 125 p
(AD-A275617; NPS-EC-93-017) Avail: CASI HC A06/MF A02

This report presents the Signal Processing and Communications (SPC) software package. SPC is an interactive package designed to provide the user with a series of data manipulation tools which use MATLAB version 4 graphical interface controls. SPC includes various filtering techniques, AutoRegressive (AR) and linear Moving Average AutoRegressive (ARMA) modeling methods, speech processing, and communication functions. SPC can be used in the classroom to illustrate and to reinforce basic concepts in signal processing and communications. It allows the user to concentrate on the principles presented in class instead of the details related to software usage. It can also be used as a basic analysis and modeling tool for research in signal processing. SPC was designed for Electrical Engineering applications. As a result, it is well suited to reinforce basic concepts presented in the following courses offered at the Naval Postgraduate School: EC 4410: Speech Processing, EC 4420: Modern Spectral Estimation, EC 3420: Statistical Digital Signal Processing, EC 3400: Digital Signal Processing, and EC 2500: Communication Theory. We hope that users will find this package useful, and we welcome any comments and suggestions regarding this software at browndw ece.nps.navy.mil (until 6/94), or fargues ece.nps.navy.mil. DTIC

CHARACTERIZATION OF A DIFFRACTION GRATING AS A SIMULANT OF A SELECTIVE FREQUENCY ANTENNA FOR RADIOMETRIC APPLICATIONS Final Report, Oct. 1991 - Oct. 1992
Thomas J. Pizzillo Jan. 1994 20 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275793; ARL-TR-303) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report details the study of a blazed diffraction grating as a simulant of a selective frequency antenna for radiometric applications. Specifically, the ability to direct and sweep a beam of millimeter wave (MMW) energy is explored as a potential means of munitions guidance. A grating was designed and built to direct incident energy into the negative first-order peak of the associated diffraction spectrum. A change of 1 GHz in the incident energy frequency is shown to produce a beam displacement of 0.30, a polarization dependence is shown to exist for energy in orders other than zero, and a limited scaling of the optical theory of diffraction to MMW energies is demonstrated to be feasible. COLLOCATED TUNABLE WAVENUMBER SENSOR/ACTUATORS FOR SMART STRUCTURES
Lori Jones 7 Feb. 1994 8 p
(Contract N00014-92-C-0214)
(AD-A275872; MML-TM-94-02) Avail: CASI HC A02/MF A01

Two actuator modules have just come out of burnout. This burnout took longer than anticipated due to power outages during January. The measurements on the smaller actuators have been repeated and agreed with the previously reported values within +/- 10%. Measurements made on a glued stack showed stiffening with increasing stress from a modulus of about 4 Mpsi at 1000 psi to 12 Mpsi at 10,000 psi applied stress -- this shows the advantage of the cofired actuator. PHOTOREFRACTIVE ADAPTIVE ANTENNA ARRAY PROCESSOR Final Report, Dec. 1990 - Jun. 1993
Robert Montgomery, William Beaudet, David Graves, Michael Lange, and Michael Luntz Dec. 1993 90 p
(Contract F30602-91-C-0005)
(AD-A275762; RL-TR-93-245) Avail: CASI HC A05/MF A01

The objective of this contract was to build a laboratory model of a six channel adaptive antenna array processor using acousto-optic delay lines with a photorefractive structure which both computes and applies the adaptive tap weights. The major performance goal of greater than 40 dB suppression for a single narrowband interferer at a fixed frequency in the band was exceeded by 10 dB suppression for narrow band interference. This substantially exceeds that attained by previous optical processors. A goal of greater than 37 dB suppression for a narrow band signal at any frequency in a 20 MHz band was also exceeded. The goal of 20 dB rejection for a signal with 10 MHz instantaneous bandwidth was met with difficulty. To meet this goal, an extensive analysis of the limitations of LMS algorithm processors was required. This analysis indicates that the system was actually performing close to theoretical limits tor this design. The analytic and experimental results are reported here. DTIC

RL/ERCT AUTOMATED SWEPT-ANGLE BISTATIC MEASUREMENT SYSTEM Report, Oct. 1985 - Jun. 1989
Marc G. Cote Apr. 1993 121 p
(AF Proj. 4600)
(AD-A275763; RL-TR-93-52) Avail: CASI HC A06/MF A02

A bistatic scattering measurement system well suited to support basic research in target scattering is described. The system can measure bistatic scattering from near backscatter through forward scatter. At X-band frequency, scattering levels of -50 dBsm in the backscattering region and -18 dBsm at forward scatter can be measured to an accuracy of +/-1 dB. This fully automated indoor system fixes the target and direction of illumination and sweeps the receive antenna to collect data as a direct function of bistatic angle. A broadband, coherent, continuous wave radar is used to obtain both amplitude and phase of the component of the total field aligned with the receive antenna polarization. Target scattered fields are derived from the phasor subtraction of target and background measurement runs. We consider the system design, calibration procedure, and measurement accuracy. Example measurements on metal cubes and spheres are presented to demonstrate the system performance. DTIC

1.8 GIGAHERTZ (GHz) DIGITAL LOW DENSITY RADIO COMMUNICATIONS LINK (LDRCL) OPERATIONAL TEST AND EVALUATION (OT&E) INTEGRATION AND OT&E OPERATIONAL FINAL TEST REPORT Technical Note
Michael R. Melillo Jan. 1994 35 p
(AD-A275800; DOT/FAA/CT-TN93/41) Avail: CASI HC A03/MF A01

This report contains the results of the Operational Test and Evaluation

(OT&E) Integration and OT&E Operational Testing of the Commercial-Off-The-Shelf (COTS) Low Density Radio Communications Link's (LDRCL) 1.8-gigahertz (GHz) digital radio system. The OT&E testing was accomplished by first testing the LDRCL equipment against its equipment specification (FAA-E-2853) and then performing OT&E testing at the key site (Miami, Florida). These tests proved that the 1.8 GHz LDRCL equipment can fulfill its mission in the National Airspace System (NAS)I, and that, it is suitable and effective. Based on the test results, it is concluded that the 1.8 GHz LDRCL equipment is qualified for operational deployment. DTIC

DEFOCUSSING CHARACTERISTICS OF THE ACTS, T1-VSAT EARTH TERMINAL ANTENNAS

Kevin M. Lambert (Analex Corp., Brook Park, OH.) and Walter M. Strickler Jan. 1994 54 p

(Contract NAS3-25776; RTOP 506-72-1C)

(NASA-TM-106420; E-8257; NAS 1.15:106420) Avail: CASI HC A04/MF A01

This report describes a study, the purpose of which was to determine the characteristics of two reflector antennas, as the reflector feed is moved away from the focus. The antennas are a 1.2 meter and a 2.44 meter reflector that will be used in the T1-VSAT earth terminals for the Advanced Communications Technology Satellite (ACTS). These terminals have been constructed in such a way that is inconvenient to use attenuators to control the gain of the signal that is directed toward the satellite. Feed defocusing was proposed as a simple, convenient way to achieve the required gain control. The study was performed in two parts. In order to determine the feasibility of the technique, a theoretical analysis was performed to obtain the gain, beamwidth and far-field pattern of the antennas, as a function of feed displacement. An experimental investigation followed in which patterns of the 1.2 meter antenna were obtained through measurement in the NASA Lewis Research Center, Near-Field Antenna Test Facility. Results of the theoretical and experimental investigation are presented for both uplink (30 GHz) and downlink (20 GHz) frequencies. Author

A COGNITIVE MODEL OF DECISION MAKING: CHUNKING AND THE RADAR DETECTION DEVICE

Constantine P. Papageorgiou and Kathleen Carley 13 Dec. 1993 29 p Sponsored by Martin Marietta Corp.

(AD-A275185; CMU-CS-93-228) Avail: CASI HC A03/MF A01

Organizational performance is an issue that pervades many aspects of our society. The value of this subject becomes evident upon realizing that most societal interactions can be regarded as interactions between different organizations. Taking this one step further, the performance of these organizations is of central importance; if bad or incorrect decisions are made most of the time, the organization will fail, whereas making a majority of good or correct decisions leads to the success of the organization. It also becomes obvious that there are many internal and external factors or stressors that can cause the performance of an organization to deteriorate. Thus, organizational performance is, in general, not constant. Training may mitigate the effect of such stressors. Training procedures are of special interest to organizations where performance is more critical than in other organizations. The targeted organizations are those which are involved in certain dangerous or critically important tasks; for example, it is easy to see that more is at stake when designing a training procedure for an agent who is guiding airplanes from a control tower than for one who is separating balls by color at a toy manufacturing plant. As such, there has been much research into identifying different training procedures and the effects of training in improving performance. A significant increase in recent research in this area has been a direct result of an instance of the identify friend or foe task where the incorrect identification of an aircraft resulted in the direct loss of more than 200 civilian lives: the 3 July 1988 tragic shooting of an Iranian passenger plane over the Persian Gulf by the U.S.S. Vincennes. DTIC

ENVIRONMENTAL CHARACTERIZATION FOR TARGET ACQUISITION. ANALYSIS OF THERMAL AND VISIBLE IMAGERY Technical Report No. 2

Bruce M. Sabol and Salvador Rivera, Jr. Nov. 1993 303 p

(AD-A275414; WES/TR/EL-93-9-2) Avail: CASI HC A14/MF A03

Automated/Aided Target Recognition (ATR) systems are being developed for client and next generation attack and reconnaissance helicopters. Part of the development cycle consists of testing and evaluation of the systems at field test facilities within the United States. Preliminary tests of ATR systems have demonstrated a high sensitivity to terrain and environmental conditions. Testers and analysts must therefore have an understanding of the relationship between system performance and terrain/environmental conditions to plan tests and interpret data. To develop an understanding of this relationship, the Environmental Characterization for Target Acquisition (ECTA) Program was initiated. As part of this program, visible and thermal infrared imagery, meteorological data and terrain characterization data were systematically collected from six different U.S. sites for different times of year and times of day. This report describes analysis procedures for evaluating the relationships between the sites' ground-truth measurements and statistical characteristics of resulting imagery. Results of these analyses are presented and discussed. DTIC

DOD ELECTRONIC COMMERCE (EC)/ELECTRONIC DATA INTERCHANGE (EDI) IN CONTRACTING REPORT

20 Dec. 1993 321 p

(AD-A275298) Avail: CASI HC A14/MF A03

Use of Electronic Commerce (EC)/Electronic Data Interchange (EDI) to support Department of Defense (DoD) procurement processes has been under consideration for some time. A 1988 Deputy Secretary of Defense memo calls for maximum use of EDI, based on 10 years of DoD EDI investigation and experiments. In 1990, Defense Management Review Decision 941 stated, 'The strategic goal of DoD's current efforts is to provide the department with the capability to initiate, conduct, and maintain its external business related transactions and internal logistics, contracting, and financial activities without requiring the use of hard copy media.' The EC in Contracting PAT membership reflected a broad cross section of Military Services and Defense Agencies working on a full-time basis for 60 days. The diversity of the EC in Contracting PAT ensured that the needs and concerns of all DoD components were addressed during the creation of the report. The resultant plan, therefore, represents a comprehensive approach for implementing EC throughout the DoD. DTIC

SPURS IN DIGITAL RADIO FREQUENCY MEMORY AND APPLICATIONS OF DRFM M.S. Thesis
B. V. Nityananda Sep. 1993 115 p
(AD-A275013) Avail: CASI HC A06/MF A02

A method to calculate the power level of harmonics generated in digital radio frequency memory (DRFM) due to sampling and quantization process is presented. The Fourier series analysis is used for the calculation of the harmonic levels. The quantization process generates the harmonics of the fundamental signal which is folded into the DRFM instantaneous bandwidth by the sampling process. Power level of the harmonics is dependent on the number of quantization bits of the analog to digital converter. It is also dependent on the ratio of signal frequency to sampling frequency. MATLAB programs for computation of harmonic power levels and plots of harmonic power levels of multibit DRFM are included in the thesis. Some applications of the DRFM, such as deception jammer, broadband frequency source, and radar simulator, are also discussed. Author (DTIC)

REMOVAL OF COHERENT EXTREMELY LOW FREQUENCY (ELF) BACKGROUND NOISE BY ADAPTIVE NOISE CANCELLATION M.S. Thesis
Samuel J. Strange 23 Sep. 1993 72 p
(AD-A275016) Avail: CASI HC A04/MF A01

The use of the sequential regression algorithm (SER) to coherently remove background noise from an ELF sensor is presented. The SER algorithm is described for a multichannel application in order to cancel coherent portions of reference sensors from a primary sensor. The algorithm adaptively accounts for differences between two parallel array platforms for the purpose of coherent subtraction. A section on likelihood ratio detector schemes for detecting narrowband signals is also presented. This work is in support of a submerged ELF sensor array project run by the Johns Hopkins University Applied Physics Lab. DTIC

ANALYSIS OF MICROWAVE INDUCED INTERFERENCE IN pn-DIODES [ANALYS AV MIKROVAGSINDUCERADE STOERNINGAR I PN-DIODER]
J. Svedin Aug. 1993 44 p In SWAHILI
(PB94-136983; FOA-C-30720-8.3; FOA-C-30720-3.2) Issuing Activity (National Technical Information Service (NTIS))

Methods for analysis of microwave induced interference in pn-diodes have been evaluated. It has been found that the effects of parasitics may significantly affect the diode susceptibility. This implies that the noise immunity of a given diode depends on the way it is mounted, and on its environment. In this work parasitics have therefore been determined by adapting reflection data to a small signal model. The microwave amplification has then been calculated, both by using a dynamic diode model directly derived from the time-dependent diffusion equation which in principle allows minority carrier recombination times of the same order as the microwave signal period time, but also (for comparison) by using the diode model in SPICE. The agreement between measurements and calculated results concerning change in bias current with a constant bias voltage when the diode is exposed to sinusoidal microwave signals has been found acceptable in regions not to close to the diode knee. Approaches for attacking the practical testing activity have also been discussed. NTIS

EVALUATION OF WIRELESS LOCAL AREA NETWORKS M.S. Thesis
Charles L. McBee Sep. 1993 138 p
(AD-A275133) Avail: CASI HC A07/MF A02

This thesis is an in-depth evaluation of the current wireless Local Area Network (LAN) technologies. Wireless LAN's consist of three technologies: they are infrared light, microwave, and spread spectrum. When the first wireless LAN's were introduced, they were unfavorably labeled slow, expensive, and unreliable. The wireless LAN's of today are competitively priced, more secure, easier to install, and provide equal to or greater than the data throughput of unshielded twisted pair cable. Wireless LAN's are best suited for organizations that move office staff frequently, buildings that have historical significance, or buildings that have asbestos. Additionally, an organization may realize a cost savings of between $300 to $1,200 each time a node is moved. Current wireless LAN technologies have a positive effect on LAN standards being developed by the Defense Information System Agency (DISA). DoD as a whole is beginning to focus on wireless LAN's and mobile communications. If system managers want to remain successful, they need to stay abreast of this technology. DTIC

STABILITY OF DYNAMICAL SYSTEMS IN THE PRESENCE OF NOISE Final Report, 12 Aug. 1991 - 31 Aug. 1993
Mark A. Pinsky and Elton P. Hsu 22 Nov. 1993 2 p
(Contract DAAL03-91-G-0311)
(AD-A275383; Rept-0650-300-L407; ARO-28905.6-MA) Avail: CASI HC A01/MF A01

Pinsky's research is concerned with the exponential growth rate (= Lyapunov exponent) of solutions of stochastic differential equations. In a paper to appear in the Annals of Applied Probability, a formula is obtained for the quadratic Lyapunov exponent of the simple harmonic oscillator in the presence of a finite-state Markov noise process. In case the noise process is reversible, the quadratic Lyapunov exponent is strictly less than

for the corresponding white noise process obtained from the central limit theorem. An example is presented of a non-reversible Markov noise process for which this inequality is reversed. In another article, to appear in the volume 'Stochastic Partial Differential Equations and their Applications' in the Springer Verlag Lecture Notes in Control and Information Sciences (Proceedings of the 1991 Charlotte NC Conference on SPDE, ed. B. Rozovskii), the Lyapunov exponent is computed for the solution of a hyperbolic partial differential equation with damping. In this case, one studies the exponential growth rate of the energy of the solution with Dirichlet boundary conditions. The detailed results depend on the size of the damping constant (overdamped vs. underdamped case). To our knowledge, this is the first study ever of the Lyapunov exponent for a partial differential equation. DTIC

ACQUISITION TIME ANALYSIS OF NONCOHERENT PN SEQUENCE ACQUISITION SCHEMES M.S. Thesis
Levent Misirlioglu 23 Sep. 1993 90 p
(AD-A275017) Avail: CASI HC A05/MF A01

In direct-sequence spread-spectrum systems, successful communications require phase synchronization of the incoming pseudonoise (PN) coded waveform with a locally generated replica at the receiver. It has been previously shown that sequential PN code acquisition schemes have the potential to achieve the best performance, but they are the least analyzed because of the analytical difficulties. The acquisition time for a PN code acquisition scheme is an important parameter for system design purposes. This thesis investigates the performance of two acquisition schemes in terms of the acquisition time. A fixed sample size (FSS) test and a truncated sequential probability ratio test (TSPRT) are studied with noncoherent demodulation in a classical additive white Gaussian noise (AWGN) channel and in presence of fading. Optimal selection of desired detection and false alarm probabilities, the effects of penalty time, majority logic verification schemes, and channel signal to noise ratio (SNR) mismatch problems are thoroughly studied using the flow graph technique. Results show that the TSPRT is efficient, robust (against fading), fast, and suitable for real time, low cost implementations. DTIC

VIDEO TRANSMISSION ON ATM NETWORKS Ph.D. Thesis
Yun-Chung Chen Dec. 1993 177 p
(Grant NAG5-1612)
(NASA-CR-195124; NAS 1.26:195124) Avail: CASI HC A09/MF A02

The broadband integrated services digital network (B-ISDN) is expected to provide high-speed and flexible multimedia applications. Multimedia includes data, graphics, image, voice, and video. Asynchronous transfer mode (ATM) is the adopted transport techniques for B-ISDN and has the potential for providing a more efficient and integrated environment for multimedia. It is believed that most broadband applications will make heavy use of visual information. The prospect of wide spread use of image and video communication has led to interest in coding algorithms for reducing bandwidth requirements and improving image quality. The major results of a study on the bridging of network transmission performance and video coding are: Using two representative video sequences, several video source models are developed. The fitness of these models are validated through the use of statistical tests and network queuing performance. A dual leaky bucket algorithm is proposed as an effective network policing function. The concept of the dual leaky bucket algorithm can be applied to a prioritized coding approach to achieve transmission efficiency. A mapping of the performance/control parameters at the network level into equivalent parameters at the video coding level is developed. Based on that, a complete set of principles for the design of video codecs for network transmission is proposed. Author (revised)

MODEL-ORIENTED ANALYSIS OF A COMMUNICATIONS PROTOCOL
J. C. Bicarregui Dec. 1993 25 p
(PB94-138146; RAL-93-099) Avail: Issuing Activity (National Technical Information Service (NTIS))

A communications protocol in CCS with value-passing is considered. A data model of the state is given in terms of the type constructors usually found in model-oriented specification. This paper considers some alternative data-models for this system: two abstractions and two reifications of the original specification are given. In particular, strong invariants are used to exclude unreachable values from the state space. VDM is used for the development, and the role of the explicit frames of reference in the operation definitions is examined in some detail. The interaction between read and write frames and invariant is studied, as is the manner by which the information in the frames is propagated during refinement. Also examined is how the use of these frames can be extended and how their use can be combined with operation structuring mechanisms available in other model-oriented methods. The paper concludes with a discussion of some general questions of methodology raised by the example. NTIS

THE 19TH CONVENTION ON RADIO SCIENCE: ABSTRACTS OF PAPERS
V. Porra and P. Alinikula Oct. 1993 101 p Conference held in Otaniemi, Finland, 25-26 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-136868; ISBN-951-22-1786-4) Avail: Issuing Activity (National Technical Information Service (NTIS))

The 19th Convention on Radio Science was held on 25-26 October, 1993, at the Faculty of Electrical Engineering of Helsinki University of Technology. The topic chosen for this year's meeting is Wireless Communications, Systems and Components--a rapidly evolving field of telecommunications. The keynote presentation of the Convention will be given by Professor Jorgen Bach Andersen, Director of the Center for Personal Communications from Aalborg University, Denmark. Moreover, two contributions from Estonia and several papers by foreign visitors in Finland will give this Convention some international flavor. Instead of the traditional Swedish or Finnish, most of the papers will be delivered in English. In addition to the main topic of the Convention, there is a session on Radio Astronomy elaborating a special field of wireless communication between man and the Universe. NTIS

DETECTION METHODS FOR STEALTH RADIO SIGNALS: A LITERATURE SURVEY
G. Andersson Aug. 1993 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0347-3708)
(PB94-137452; FOA-C-30724-8.3) Avail: CASI HC A03

In military radio communication systems, a central feature is often the ability to avoid discovery by some hostile interceptor. Therefore, when designing such a stealth radio system, it is naturally important to have knowledge of the different existing signal detection methods, i.e., the threats to a stealth radio system. This report is a literature survey of some of the most interesting methods of detecting different types of digitally modulated radio communication signals. The methods covered are wide-band radiometer detection, optimum detection and cyclic-feature detection. Comparisons between the different methods are also performed. NTIS

SUBPHONETIC ACOUSTIC MODELING FOR SPEAKER-INDEPENDENT CONTINUOUS SPEECH RECOGNITION Ph.D. Thesis

Mei-Yuh Hwang 17 Dec. 1993 176 p
(Contract N00014-93-1-2005)
(AD-A275217; CMU-CS-93-230) Avail: CASI HC A09/MF A02

To model the acoustics of a large vocabulary well while staying within a reasonable memory capacity, most speech recognition systems use phonetic models to share parameters across different words in the vocabulary. This dissertation investigates the merits of modeling at the subphonetic level. We demonstrate that sharing parameters at the subphonetic level provides more accurate acoustic models than sharing at the phonetic level. The concept of subphonetic parameter sharing can be applied to any class of parametric models. Since the first-order hidden Markov model (HMM) has been overwhelmingly successful in speech recognition, this dissertation bases all its studies and experiments on HMM's. The subphonetic unit we investigate is the state of phonetic HMM's. We develop a system in which similar Markov states of phonetic models share the same Markov parameters. The shared parameter (i.e., the output distribution) associated with a cluster of similar states is called a senone because of its state dependency. The phonetic models that share senones are shared-distribution models or SDM's. Experiments show that SDM's offer more accurate acoustic models than the generalized-triphone model presented by Lee. Senones are next applied to offer accurate models for triphones not experienced in the system training data. In this dissertation, two approaches for modeling unseen triphones are studied - purely decision-tree based senones and a hybrid approach using the concept of Markov state quantization. Both approaches indeed offer a significant error reduction over the previously accepted approach of monophone model substitution. However, the purely decision-tree based senone approach is preferred for its simplicity. DTIC

DEPLOYABLE REFLECTOR STRUCTURE Patent Application
Martin Mikulas, Jr., inventor (to NASA) and Charles Hoberman, inventor (to NASA) 23 Sep. 1993 27 p
(NASA-Case-LAR-14513-1-SB; NAS 1.71:LAR-14513-1-SB; US-Patent-Appl-SN-126286) Avail: CASI HC A03/MF A01

A deployable reflector structure is presented. The structure has a number of movable reflector panels pivotably supported on rigid arms. Several such arms are pivotably connected to a central structure. The arm can move in starburst fashion from a packaged stage, where all arms are vertical, to a deployed stage, where all arms are horizontal. All of the movable reflector panels are maintained at a predetermined angle to an axis of the reflector structure when the arms are pivoted. The reflector panels are stacked tightly on top of each other in the packaged state of the reflector structure. Simple mechanisms are used for avoiding interference between panels on different arms in the packaged stage and for fitting the movable panels together like tiles in the deployed stage. NASA

DEVELOPMENT OF ELECTROMAGNETIC COMPATIBILITY TESTS [L'EVOLUTION DES ESSAIS DE COMPATIBILITE ELECTROMAGNETIQUE]
B. Raveu 1993 5 p In FRENCH Presented at Astelab, Paris, France, 16 Jun. 1992
(Rept-932-430-110; ETN-94-95468) Avail: CASI HC A01/MF A01

Evolutions in the domain of electromagnetic compatibility tests are addressed. It is reported that there is an increasing demand in the frequency and power domains, and that new conducted signals have been generated. In order to respond to the needs of the users, test facilities show an increase in the frequency domain from 10 to 40 GHz, and an increase in the intensity of the field from 10 to 300 V/m. The test engineers must follow these developments and abide by the different standards. Requirements that concern the surroundings of the objects in test which must be added are considered: for example a clean atmosphere. These new facilities are now set up and they must be used with proceedings that permit traps to be avoided and the results of the equipment tests to be made significant and credible. ESA

THEORETICAL AND EXPERIMENTAL STUDY OF A CYLINDRICAL MICROSTRIP ANTENNA
M. Monaco (Nice Univ., France.), G. Ghio (Nice Univ., France.), E. Cambiaggio (Nice Univ., France.), J. P. Boisset, M. Sauvan, and B. Buralli 1993 5 p
(Rept-932-440-109; ETN-94-95479) Avail: CASI HC A01/MF A01

A low profile microstrip belt antenna concept was developed and tested. The antenna radiation pattern was optimized. The antenna is suitable for optimal air or space based reception of radio localized signals. The antenna, along with a 3.78 bandwidth, offers ripple within +/- 2 dB and 98 percent coverage probability. The system was conceived to receive the global positioning system radio signals beamed from the navigation system by time and range satellite network. The resulting microstrip belt antenna is a low cost, low profile, low weight, and easy integration antenna concept. ESA

Multiprocessor architectures are needed to support modern broadband

applications, since traditional bus structures are not capable of providing high throughput. New bus structures are needed, especially in the area of network components and terminals. A study to find an efficient and cost effective interconnection topology for the future high speed products is presented. The most common bus topologies are introduced, and their characteristics are estimated to decide which one of them offers best performance and lowest implementation cost. The ring topology is chosen to be studied in more detail. Four competing bus access schemes for the high throughput ring are introduced as well as simulation models for each of them. Using transfer delay and throughput results, as well as keeping the implementation point of view in mind, the best candidate is selected to be studied and experimented in the succeeding research project. EXTENDED HORIZON LIFTING FOR PERIODIC GAIN ADJUSTMENT IN CONTROL SYSTEMS, AND FOR EQUALIZATION OF COMMUNICATION CHANNELS Patent Application

David S. Bayard, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 16 Mar. 1994 44 p

(Contract NAS7-1260)

(NASA-Case-NPO-19166-1-CU; NAS 1.71:NPO-19166-1-CU;

US-Patent-Appl-SN-222762) Avail: CASI HC A03/MF A01

Periodic gain adjustment in plants of irreducible order, n, or for equalization of communications channels is effected in such a way that the plant (system) appears to be minimum phase by choosing a horizon time N is greater than n of liftings in periodic input and output windows rho sub u and rho sub y, respectively, where N is an integer chosen to define the extent (length) of each of the windows rho sub u and rho sub y, and n is the order of an irreducible input/output plant. The plant may be an electrical, mechanical, or chemical system, in which case output tracking (OT) is carried out for feedback control or a communication channel, in which case input tracking (IT) is performed. Conditions for OT are distinct from IT in terms of zero annihilation, namely H(sub s)H(sub s)(sup +) = I for OT and H(sub s)H(sub s)(sup +) = I of IT, where the OT conditions are intended for gain adjustments in the control system, and IT conditions are intended for equalization for communication channels.

AN INVESTIGATION OF DISTRIBUTED COUPLING IN A NONLINEAR SEMICONDUCTOR WAVEGUIDE Ph.D. Thesis

David Floyd Prelewitz 1993 274 p

Avail: Univ. Microfilms Order No. DA9313879

In this thesis, we theoretically and experimentally analyze the nonlinear coupling properties of a model waveguide-grating structure. A planar Si-on-insulator (SOI) structure with a periodic distributed grating coupler is used as the model system. Unlike other optoelectronic materials, Si does not possess a direct band gap or a linear electro-optic effect. However, it may be possible to utilize silicon's large free carrier effect in optoelectronic devices. It may also be possible to integrate Si optical structures with Si based electronic circuits on monolithic substrates. In an experimental study of the SOI structure, a distributed grating input coupler is used to transfer light from a Nd:YAG Q-switched laser (lambda(sub 0) = 1.064 microns) into the guiding region by exciting TE(sub 0) modes. Temporal changes in the waveguide mode pulse profiles are then measured with a digital sampling oscilloscope (DSO). Linear and nonlinear coupling measurements are made using various input conditions in an attempt to characterize the structure. From observations, power dependent optical limiting and damped oscillations are evident in the pulse profiles. By numerically modeling the structure, we attribute the temporal fluctuations in the mode profile to intensity dependent changes in the refractive index of the Si guiding layer. Contributions to the refractive index from both free carrier and thermal changes are considered. Rapid index variations cause the propagation wavevector in the interaction region to be power dependent. As a result, the coherent optical coupling properties of the structure are altered. We have determined that spatial changes in the resonance condition of the coupling structure accounts for most of the limiting effects. Damped oscillations observed in the temporal pulse profile are attributed to interference effects induced by a nonlinear phase shift in the guided mode. The numerical computations indicate that the nonlinear coupling process is dominated by free carrier effects. However, competition between electronic and thermal processes becomes more acute with higher energies. By fully modeling the two dimensional carrier and thermal dynamics, we are able to fully characterize the nonlinear coupling process due to the material and geometric constraints. Dissert. Abstr.

AUTOMATIC FOCUS AND REGISTRATION OF SYNTHETIC APERTURE RADAR IMAGES Ph.D. Thesis

Terry Marshall Calloway 1992 235 p

Avail: Univ. Microfilms Order No. DA9315929

A tomographic model explains why aperture phase error produces cross-range blur. New algorithms estimate phase error then correct it to remove blur from a synthetic aperture radar (SAR) image. A new sinusoidal map drift autofocus (SMDA) algorithm removes high-order (greater than five) phase error better than a conventional polynomial map drift autofocus (PMDA) algorithm. A new least squares autofocus (LSA) algorithm focuses an image in fewer iterations than required by a conventional phase gradient autofocus (PGA) algorithm. A new algorithm aligns, or registers, a complex valued SAR image with a reference SAR image. Tests indicate that the algorithm can achieve simultaneously RMS errors of 0.01 degree, 0.03 pixel, and 0.01 percent in rotation, translation, and scale, respectively.

GLRS-R 2-COLOUR RETROREFLECTOR TARGET DESIGN AND PREDICTED PERFORMANCE

Glenn Lund 1993 17 p See also N94-15615

(Rept-932-440-106; ETN-94-95476) Avail: CASI HC A03/MF A01

The retroreflector ground target design for the GLRS-R spaceborne dual wavelength laser ranging system is described. The passive design flows down from the requirements of high station autonomy, high global field of view, little or no multiple pulse returns, and adequate optical cross section for most ranging geometries. The solution makes use of five hollow cube corner retroreflectors of which one points to the zenith and the remaining four are inclined from the vertical at uniform azimuthal spacings. The need for large retroreflectors is expected to generate narrow diffraction lobes. A good compromise solution is found by spoiling just one of the retroereflector dihedral angles from 90 deg, thus generating two symmetrically oriented diffraction lobes in the return beam. The required spoil angles are found to have little dependance on ground target latitude. Various link budget analyses are presented. They show the influence of such factors as point ahead optimization, turbulence, ranging angle, atmospheric visibility, and ground target thermal deformations. ESA

NON-ORTHOGONAL SUBBAND/TRANSFORM CODER Patent Application

Daniel R. Glover, inventor (to NASA) 15 Dec. 1993 28 p

(NASA-Case-LEW-15310-1; NAS 1.71:LEW-15310-1;

US-Patent-Appl-SN-167107) Avail: CASI HC A03/MF A01

The present invention is directed to a simplified digital subband coder/decoder. In the present invention a signal is fed into a coder. The coder uses a non-orthogonal algorithm that is simply implemented in the coder hardware. The simple non-orthogonal design is then used in the implementation of the decoder to decode the signal. THE TELECOMMUNICATIONS AND DATA ACQUISITION REPORT Progress Report, Jan. - Mar. 1991

Edward C. Posner, ed. 15 May 1991 160 p

(Contract NAS7-918)

(NASA-CR-195694; JPL-TDA-PR-42-105; NAS 1.26:195694) Avail: CASI HC A08/MF A02

This quarterly publication provides archival reports on developments in programs managed by JPL's Office of Telecommunications and Data Acquisition (TDA). In space communications, radio navigation, radio science, and ground-based radio and radar astronomy, it reports on activities of the Deep Space Network (DSN). Also included is standards activity at JPL for space data and information systems and reimbursable DSN work performed for other space agencies through NASA. In the search for extraterrestrial intelligence (SETI), 'The TDA Progress Report' reports on implementation and operations for searching the microwave spectrum. In solar system

radar, it reports on the uses of the Goldstone Solar System Radar for scientific exploration of the planets, their rings and satellites, asteroids, and comets. In radio astronomy, the areas of support include spectroscopy, very long baseline interferometry, and astrometry. For individual titles, see N94-29614 through N94-29626.

COMBINING GPS AND VLBI EARTH-ROTATION DATA FOR IMPROVED UNIVERSAL TIME **c04**
A. P. Freedman *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 1-12 (For primary document see N94-29613 08-32)
(RTOP 310-10-61-87-02)
Avail: CASI HC A03/MF A02

The Deep Space Network (DSN) routinely measures Earth orientation in support of spacecraft tracking and navigation using very long-baseline interferometry (VLBI) with the deep-space tracking antennas. The variability of the most unpredictable Earth-orientation component, Universal Time 1 (UT1), is a major factor in determining the frequency with which the DSN measurements must be made. The installation of advanced Global Positioning System (GPS) receivers at the DSN sites and elsewhere may soon permit routine measurements of UT1 variation with significantly less dependence on the deep-space tracking antennas than is currently required. GPS and VLBI data from the DSN may be combined to generate a precise UT1 series, while simultaneously reducing the time and effort the DSN must spend on platform-parameter calibrations. This combination is not straightforward, however, and a strategy for the optimal combination of these data is presented and evaluated. It appears that, with the aid of GPS, the frequency of required VLBI measurements of Earth orientation could drop from twice weekly to once per month. More stringent real-time Earth orientation requirements possible in the future would demand significant improvements in both VLBI and GPS capabilities, however. Author

COMPUTATION OF VIBRATION MODE ELASTIC-RIGID AND EFFECTIVE WEIGHT COEFFICIENTS FROM FINITE-ELEMENT COMPUTER PROGRAM OUTPUT **c39**
R. Levy *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 13-20 (For primary document see N94-29613 08-32)
(RTOP 310-20-65-86-04)
Avail: CASI HC A02/MF A02

Post-processing algorithms are given to compute the vibratory elastic-rigid coupling matrices and the modal contributions to the rigid-body mass matrices and to the effective modal inertias and masses. Recomputation of the elastic-rigid coupling matrices for a change in origin is also described. A computational example is included. The algorithms can all be executed by using standard finite-element program eigenvalue analysis output with no changes to existing code or source programs. Author

X-/Ka-BAND DICHROIC PLATE DESIGN AND GRATING LOBE STUDY
J. C. Chen *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 21-30 (For primary document see N94-29613 08-32)
(RTOP 310-20-64-89-01)
Avail: CASI HC A02/MF A02

An X-/Ka-band dichroic plate is needed for simultaneously receiving X-band and Ka-band in the DSS-13 Beam Waveguide Antenna. The plate is transparent to the allocated Ka-band downlink (31.8-32.3 GHz) and the frequency band for the Mars Observer Ka-band Beacon Link Experiment (KABLE) (33.6-33.8 GHz), while at the same time reflecting the X-band downlink (8.4-8.5 GHz). The design is made using a computer program for dichroic plates with rectangular holes. The theoretical performance of the X-/Ka-band dichroic plate is presented. A study of the grating lobe problem is also included in this article. Author

MODIFICATIONS OF THE GRIESMER BOUND **c61**
R. J. McEliece (California Inst. of Tech., Pasadena.) and G. Solomon (Solomon, G., Pasadena, CA.) *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 41-44 (For primary document see N94-29613 08-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A01/MF A02

The Griesmer bound is a classical technique (developed in 1960) for estimating the minimum length n required for a binary linear code with a given dimension k and minimum distance d. In this article, a unified derivation of the Griesmer bound and two new variations on it are presented. The first variation deals with linear codes which contain the all-ones vector; such codes are quite common and are useful in practice because of their 'transparent' properties. The second variation deals with codes that are constrained to contain a word of weight greater than or equal to M. In both cases these constraints (the all-ones word or a word of high weight) can increase the minimum length of a code with given k and d.

INTEGER COSINE TRANSFORM FOR IMAGE COMPRESSION **c61**
K.-M. Cheung, F. Pollara, and M. Shahshahani *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 45-53 (For primary document see N94-29613 08-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A02/MF A02

This article describes a recently introduced transform algorithm called the integer cosine transform (ICT), which is used in transform-based data compression schemes. The ICT algorithm requires only integer operations on small integers and at the same time gives a rate-distortion performance comparable to that offered by the floating-point discrete cosine transform (DCT). The article addresses the issue of implementation complexity, which is of prime concern for source coding applications of interest in deep-space communications. Complexity reduction in the transform stage of the compression scheme is particularly relevant, since this stage accounts for most (typically over 80 percent) of the computational load. Author

A PORTABLE X-BAND FRONT-END TEST PACKAGE FOR BEAM-WAVEGUIDE ANTENNA PERFORMANCE EVALUATION. PART 2: TESTS ON THE ANTENNA
T. Y. Otoshi, S. R. Stewart, and M. M. Franco *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 54-68 (For primary document see N94-29613 08-32)
(RTOP 310-30-69-88-04)
Avail: CASI HC A03/MF A02

Results are given for an X-band (8.45 GHz) test package for testing the new 34-m beam-waveguide antenna at Goldstone in an 'on-the-antenna' configuration. Included are X-band zenith noise temperature values and tipping-curve data obtained at the Cassegrain focal point F1 as well as at the pedestal room focal point F3. Subreflector Z-defocus test results for both F1 and F3 are also presented. The X-band test package operated well in all of the different test configurations and exceeded expected performance. PHASING THE VERY LARGE ARRAY ON GALILEO IN THE PRESENCE OF JUPITER'S STRONG RADIO EMISSION **c17**
J. S. Ulvestad *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 69-82 (For primary document see N94-29613 08-32)
(RTOP 314-40-31-30-03)
Avail: CASI HC A03/MF A02

Work is in progress to determine the feasibility of using the Very Large Array (VLA) radio telescope to receive telemetry from Galileo during its close encounter with Io on 7 Dec. 1995. The VLA was used previously to receive telemetry from Voyager 2 at Neptune. However, Jupiter's strong radio emission is an additional complication in the case of the Galileo encounter. This article analyzes the effect of Jupiter's radio emission on the phase-adjustment procedure ('autophasing') used to maintain coherence among the 27 VLA antennas. Results of an experiment designed to mimic the Io encounter are presented. As expected, Jupiter's strong radio emission has a considerable effect on the autophasing procedure. A simple emission model is found to give a good approximation to the fringe-visibility plots derived from the VLA data, and that successful model is used to estimate the VLA's ability to autophase on Galileo during the Io encounter. The effect of Jupiter should be small for projected baselines longer than approximately 800 m and completely negligible for projected baselines longer than approximately 1.1 km. The most extended configuration of the VLA (the A configuration) probably can be used successfully for telemetry reception during the Io encounter. Further analysis and testing of the effect of correlated noise from Jupiter is necessary before a final decision can be made about the feasibility of using the second largest (B) configuration of the VLA for reception of Galileo telemetry. Use of the B configuration could simplify the upgrades needed to support the Io encounter. Tests to help choose the preferred VLA configuration could be performed by using the VLA to observe the Magellan spacecraft at Venus during Jul. and Oct. 1991. Examination of the effects of planet noise on the VLA have implications beyond the use of that telescope for supporting the Io encounter. The effects of planet radio emission on spacecraft data received by antenna arrays are relevant to choosing the exact locations of antennas that might be built by the Deep Space Network in coming years. ELEVATION CONTROL SYSTEM MODEL FOR THE DSS 13 ANTENNA **c37**
W. Gawronski and J. A. Mellstrom *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 83-108 (For primary document see N94-29613 08-32)
(RTOP 314-40-42-10-40)
Avail: CASI HC A03/MF A02

In order to meet the requirements for precision pointing of 34-m antennas, adequate control design and simulation software have to be developed along with a detailed description of the supporting analytical tools. This article describes a control system model for the elevation drive of the DSS 13 antenna. The model allows one to simulate elevation dynamics, cross-coupled dynamics in azimuth and elevation, and RF pointing error. A modal state-space model of the antenna structure was obtained from its finite-element model with a free rotating tipping structure. Model reduction techniques were applied separately for the antenna model and rate-loop model, thereby reducing the system order to one-third of the original one while preserving its dynamic properties. Extensive simulation results illustrate properties of the model. Author (revised)

RADIO SCIENCE GROUND DATA SYSTEM FOR THE VOYAGER-NEPTUNE ENCOUNTER, PART 1
E. R. Kursinski and S. W. Asmar *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 109-127 (For primary document see N94-29613 08-32)
(RTOP 314-40-41-10-13)
Avail: CASI HC A03/MF A02

The Voyager radio science experiments at Neptune required the creation of a ground data system array that includes a Deep Space Network complex, the Parkes Radio Observatory, and the Usuda deep space tracking station. The performance requirements were based on experience with the previous Voyager encounters, as well as the scientific goals at Neptune. The requirements were stricter than those of the Uranus encounter because of the need to avoid the phase-stability problems experienced during that encounter and because the spacecraft flyby was faster and closer to the planet than previous encounters. The primary requirement on the instrument was to recover the phase and amplitude of the S- and X-band (2.3 and 8.4 GHz) signals under the dynamic conditions encountered during the occultations. The primary receiver type for the measurements was open loop with high phase-noise and frequency stability performance. The receiver filter bandwidth was predetermined based on the spacecraft's trajectory and frequency uncertainties. Author

GAUSSIAN BEAM AND PHYSICAL OPTICS ITERATION TECHNIQUE FOR WIDEBAND BEAM WAVEGUIDE FEED DESIGN **c74**
W. Veruttipong, J. C. Chen, and D. A. Bathker *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 128-135 (For primary document see N94-29613 08-32)
(RTOP 314-30-50-12-78)
Avail: CASI HC A02/MF A02

The Gaussian beam technique has become increasingly popular for wideband beam waveguide (BWG) design. However, it is observed that the Gaussian solution is less accurate for smaller mirrors (approximately less than 30 lambda in diameter). Therefore, a high-performance wideband BWG design cannot be achieved by using the Gaussian beam technique alone. This article demonstrates a new design approach by iterating Gaussian beam and BWG parameters simultaneously at various frequencies to obtain a wideband BWG. The result is further improved by comparing it with physical optics results and repeating the iteration. Author

DESIGN AND ANALYSIS OF A LOW-LOSS LINEAR ANALOG PHASE MODULATOR FOR DEEP SPACE SPACECRAFT X-BAND TRANSPONDER APPLICATIONS
N. R. Mysoor and R. O. Mueller *In its* The Telecommunications and Data Acquisition Report 15 May 1991 p 136-145 (For primary document see N94-29613 08-32)
(RTOP 314-30-55-30-01)
Avail: CASI HC A02/MF A02

This article summarizes the design concepts, analyses, and development of an X-band (8145 MHz) transponder low-loss linear phase modulator for deep space spacecraft applications. A single-section breadboard circulator-coupled reflection phase modulator has been analyzed, fabricated, and evaluated. A linear phase deviation of 92 deg with a linearity tolerance of +/- 8 percent was measured for this modulator from 8257 MHz to 8634 MHz over the temperature range -20 to 75 C. The measured insertion loss and the static delay variation with temperature were 2 +/- 0.3 dB and 0.16 psec/ C, respectively. Based on this design, cascaded sections have been modeled, and simulations were performed to provide an X-band deep space transponder (DST) phase modulator with +/- 2.5 radians (+/- 143 deg) of peak phase deviation to accommodate downlink signal modulation with composite telemetry data and ranging, with a deviation linearity tolerance of +/- 8 percent and insertion loss of less than 10 +/- 0.5 dB. A two-section phase modulator using constant gamma hyperabrupt varactors and an efficient modulator driver circuit was breadboarded. The measured results satisfy the DST phase-modulator requirements and show excellent agreement with the predicted results. Author (revised)

(RTOP 906-76-40-43-01)
Avail: CASI HC A01/MF A02

In order to increase the usefulness of Goldstone orbital debris observations, several improvements are planned to the experimental Goldstone radar. The first improvement is to add a ranging capability of 1-km accuracy to the radar. This would provide much more detailed information about whatever debris is observed. The second improvement is to widen the bandwidth of the system from 10 kHz to 85 kHz so that particles in more elliptical orbits can be monitored. The two antennas could then also be pointed away from the zenith, say south, where orbits of lesser inclination might also be observed. In any case, the addition of ranging requires a substantial increase of system bandwidth. This article describes the instrumentation necessary to achieve this, together with required signal-processing modifications. Author (revised)

TOWARD ASTROMETRIC TRACKING WITH THE INFRARED SPATIAL INTERFEROMETER **c89**
R. N. Treuhaft, M. Bester, W. C. Danchi, and C. H. Townes *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 1-9 (For primary document see N94-29652 08-32)
(RTOP 310-10-60-90-03)
Avail: CASI HC A02/MF A03

Infrared interferometric demonstrations with the University of California, Berkeley's infrared spatial interferometer (ISI) on Mt. Wilson explore the potential of infrared and optical astrometry for deep space tracking, reference frame development, and DSN science. Astrometric data taken and analyzed over the last five years from the ISI have shown that instrumental and atmospheric effects limit current demonstrations. The benefits of sensitivity upgrades, which were performed in 1991 and 1992, have been demonstrated by comparing point-to-point phase fluctuations for the fall 1989 and fall 1992 observing epochs. This comparison showed that point-to-point phase fluctuations due to tropospheric and quantum noise, for optimal integration times of 0.2 sec, are approaching the 0.1-cycle level needed to reliably connect the interferometric phase. The increase in sensitivity, coupled with that arising from very recent hardware upgrades, will greatly enhance phase-connection capabilities necessary for astrometry in the presence of atmospheric refractivity fluctuations. The current data set suggests that atmospheric fluctuations on Mt. Wilson during the best seeing are dominated by a low-lying component, approximately 25 m high, which may be minimized with in situ calibration in the future. During poor seeing conditions that currently prohibit the interferometric phase connection necessary for astrometry, fluctuations seem to be generated by atmospheric inhomogeneities at much higher altitudes above Mt. Wilson. Data taken over the last year suggest that the ISI will soon be able to achieve 50- to 100-nrad astrometry in a single observing session, employing current ground-based laser distance interferometer calibrations to minimize atmospheric effects. Tropospheric inhomogeneities limit the accuracy with which a path delay in an arbitrary direction can be estimated from calibration measurements in different directions. This article demonstrates a mathematical procedure that has the potential for minimizing errors in the estimated geometrical and tropospheric path delays. The error is minimized by applying least-squares estimation to a combined set of observables in the calibration directions and the direction to be calibrated. A simulated test of this procedure was conducted using a model set of error-free calibration measurements. In the absence of geometrical delay mismodeling, the simulation yielded delay errors which vary from about 1 mm at zenith to about 1 cm at 10 degrees. The main principles of how this procedure could be applied to improve accuracy of deep space tracking using global positioning system (GPS) data are also discussed. Author (revised)

ENHANCED ORBIT DETERMINATION FILTER SENSITIVITY ANALYSIS: ERROR BUDGET DEVELOPMENT **c13**
J. A. Estefan and P. D. Burkhart *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 24-36 (For primary document see N94-29652 08-32)
(RTOP 310-10-63-50-00)
Avail: CASI HC A03/MF A03

An error budget analysis is presented which quantifies the effects of different error sources in the orbit determination process when the enhanced orbit determination filter, recently developed, is used to reduce radio metric data. The enhanced filter strategy differs from more traditional filtering methods in that nearly all of the principal ground system calibration errors affecting the data are represented as filter parameters. Error budget computations were performed for a Mars Observer interplanetary cruise scenario for cases in which only X-band (8.4-GHz) Doppler data were used to determine the spacecraft's orbit, X-band ranging data were used exclusively, and a combined set in which the ranging data were used in addition to the Doppler data. In all three cases, the filter model was assumed to be a correct representation of the physical world. Random nongravitational accelerations were found to be the largest source of error contributing to the individual error budgets. Other significant contributors, depending on the data strategy used, were solar-radiation pressure coefficient uncertainty, random earth-orientation calibration errors, and Deep Space Network (DSN) station location uncertainty. Author (revised)

ENHANCED ORBIT DETERMINATION FILTER: INCLUSION OF GROUND SYSTEM ERRORS AS FILTER PARAMETERS **c13**
W. C. Masters, D. J. Scheeres, and S. W. Thurman *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 37-41 (For primary document see N94-29652 08-32)
(RTOP 310-10-63-50-00)
Avail: CASI HC A01/MF A03

The theoretical aspects of an orbit determination filter that incorporates ground-system error sources as model parameters for use in interplanetary navigation are presented in this article. This filter, which is derived from sequential filtering theory, allows a systematic treatment of errors in calibrations of transmission media, station locations, and earth orientation models associated with ground-based radio metric data, in addition to the modeling of the spacecraft dynamics. The discussion includes a mathematical description of the filter and an analytical comparison of its characteristics with more traditional filtering techniques used in this application. The analysis in this article shows that this filter has the potential to generate navigation products of substantially greater accuracy than more traditional filtering procedures. Author

DETERMINING NOISE TEMPERATURES IN BEAM WAVEGUIDE SYSTEMS
W. Imbriale, W. Veruttipong, T. Otoshi, and M. Franco *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 42-52 (For primary document see N94-29652 08-32)
(RTOP 310-20-65-86-08)
Avail: CASI HC A03/MF A03

A new 34-m research and development antenna was fabricated and tested as a precursor to introducing beam waveguide (BWG) antennas and Ka-band (32 GHz) frequencies into the NASA/JPL Deep Space Network. For deep space use, system noise temperature is a critical parameter. There are thought to be two major contributors to noise temperature in a BWG system: the spillover past the mirrors, and the conductivity loss in the walls. However, to date, there are no generally accepted methods for computing noise temperatures in a beam waveguide system. An extensive measurement program was undertaken to determine noise temperatures in such a system along with a correspondent effort in analytic prediction. Utilizing a very sensitive radiometer, noise temperature measurements were made at the Cassegrain focus, an intermediate focal point, and the focal point in the basement pedestal room. Several different horn diameters were used to simulate different amounts of spillover past the mirrors. Two analytic procedures were developed for computing noise temperature, one utilizing circular waveguide modes and the other a semiempirical approach.

The results of both prediction methods are compared to the experimental data. Author

Avail: CASI HC A03/MF A03

The Faraday anomalous dispersion optical filter may provide ultra-high background noise rejection for free-space laser communications systems. The theoretical model for the filter is reported. The experimental measurements and their comparison with theoretical results are discussed. The results show that the filter can provide a 56-dB solar background noise rejection with about a 2-GHz transmission bandwidth and no image degradation. To further increase the background noise rejection, a composite Zeeman and Faraday anomalous dispersion optical filter is designed and experimentally demonstrated. Author

A DIGITAL COMBINING-WEIGHT ESTIMATION ALGORITHM FOR BROADBAND SOURCES WITH THE ARRAY FEED COMPENSATION SYSTEM
V. A. Vilnrotter and E. R. Rodemich *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 86-97 (For primary document see N94-29652 08-32)
(RTOP 310-30-70-89-01)
Avail: CASI HC A03/MF A03

An algorithm for estimating the optimum combining weights for the Ka-band (33.7-GHz) array feed compensation system was developed and analyzed. The input signal is assumed to be broadband radiation of thermal origin, generated by a distant radio source. Currently, seven video converters operating in conjunction with the real-time correlator are used to obtain these weight estimates. The algorithm described here requires only simple operations that can be implemented on a PC-based combining system, greatly reducing the amount of hardware. Therefore, system reliability and portability will be improved. Author

CONVOLUTIONAL ENCODING OF SELF-DUAL CODES **c61**
G. Solomon *In* JPL, The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 110-113 (For primary document see N94-29652 08-32)
(RTOP 310-30-71-83-02)
Avail: CASI HC A01/MF A03

There exist almost complete convolutional encodings of self-dual codes, i.e., block codes of rate 1/2 with weights w, $w = 0 \bmod 4$. The codes are of length 8m with the convolutional portion of length 8m-2 and the nonsystematic information of length 4m-1. The last two bits are parity checks on the two (4m-1) length parity sequences. The final information bit complements one of the extended parity sequences of length 4m. Solomon and van Tilborg have developed algorithms to generate these for the Quadratic Residue (QR) Codes of lengths 48 and beyond. For these codes and reasonable constraint lengths, there are sequential decodings for both hard and soft decisions. There are also possible Viterbi-type decodings that may be simple, as in a convolutional encoding/decoding of the extended Golay Code. In addition, the previously found constraint length $K = 9$ for the QR (48, 24;12) Code is lowered here to $K = 8$.

Avail: CASI HC A02/MF A03

The Galileo mission was originally designed to investigate Jupiter and its moons utilizing a high-rate, X-band (8415 MHz) communication downlink with a maximum rate of 134.4 kb/sec. However, following the failure of the high-gain antenna (HGA) to fully deploy, a completely new communication link design was established that is based on Galileo's S-band (2295 MHz), low-gain antenna (LGA). The new link relies on data compression, local and intercontinental arraying of antennas, a (14,1/4) convolutional code, a (255,M) variable-redundancy Reed-Solomon code, decoding feedback, and techniques to reprocess recorded data to greatly reduce data losses during signal acquisition. The combination of these techniques will enable return of significant science data from the mission. Author (revised)

DECODER SYNCHRONIZATION FOR DEEP SPACE MISSIONS
J. I. Statman, K.-M. Cheung, T. H. Chauvin, J. Rabkin, and M. L. Belongie *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 121-127 (For primary document see N94-29652 08-32)
(RTOP 314-30-61-02-01)
Avail: CASI HC A02/MF A03

The Consultative Committee for Space Data Standards (CCSDS) recommends that space communication links employ a concatenated, error-correcting, channel-coding system in which the inner code is a convolutional (7,1/2) code and the outer code is a (255,223) Reed-Solomon code. The traditional implementation is to perform the node synchronization for the Viterbi decoder and the frame synchronization for the Reed-Solomon decoder as separate, sequential operations. This article discusses a unified synchronization technique that is required for deep space missions that have data rates and signal-to-noise ratios (SNR's) that are extremely low. This technique combines frame synchronization in the bit and symbol domains and traditional accumulated-metric growth techniques to establish a joint frame and node synchronization. A variation on this technique is used for the Galileo spacecraft on its Jupiter-bound mission.

A COMPARISON OF FULL-SPECTRUM AND COMPLEX-SYMBOL COMBINING TECHNIQUES FOR THE GALILEO S-BAND MISSION
S. Million, B. Shah, and S. Hinedi *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 128-162 (For primary document see N94-29652 08-32)
(RTOP 314-30-63-03-19)
Avail: CASI HC A03/MF A03

Full-spectrum combining (FSC) and complex-symbol combining (CSC) are two antenna-arraying techniques being considered for the Galileo spacecraft's upcoming encounter with Jupiter. This article describes the performance of these techniques in terms of symbol signal-to-noise ratio

(SNR) degradation and symbol SNR loss. It is shown that both degradation and loss are approximately equal at low values of symbol SNR but diverge at high SNR values. For the Galileo S-band (2.2 to 2.3 GHz) mission, degradation provides a good estimate of performance as the symbol SNR is typically below -5 dB. For the following arrays - two 70-m antennas, one 70-m and one 34-m antenna, one 70-m and two 34-m antennas, and one 70-m and three 34-m antennas - it is shown that FSC has less degradation than CSC when the subcarrier and symbol window-loop bandwidth products are above 3.0, 10.0, 8.5, and 8.2 mHz at the symbol rate of 200 sym/sec, and above 1.2, 4.5, 4.0, and 3.5 mHz at a symbol rate of 400 sym/sec, respectively. Moreover, for an array of four 34-m antennas, FSC has less degradation than CSC when the subcarrier and symbol window-loop bandwidth products are above 0.32 mHz at the symbol rate of 50 sym/sec and above 0.8 mHz at the symbol rate of 25 sym/sec. Results of operational orbit determination, performed as part of the TOPEX/POSEIDON (T/P) Global Positioning System (GPS) demonstration experiment, are presented in this article. Elements of this experiment include the GPS satellite constellation, the GPS demonstration receiver on board T/P, six ground GPS receivers, the GPS Data Handling Facility, and the GPS Data Processing Facility (GDPF). Carrier phase and P-code pseudorange measurements from up to 24 GPS satellites to the seven GPS receivers are processed simultaneously with the GDPF software MIRAGE to produce orbit solutions of T/P and the GPS satellites. Daily solutions yield subdecimeter radial accuracies compared to other GPS, LASER, and DORIS precision orbit solutions. Author

Avail: CASI HC A03/MF A03

Design, modeling, analysis, and simulation of a phase-locked loop (PLL) with a digital loop filter are presented in this article. A TMS320C25 digital signal processor (DSP) is used to implement this digital loop filter. In order to keep the compatibility, the main design goal was to replace the analog PLL (APLL) of the Deep-Space Transponder (DST) receiver breadboard's loop filter with a digital loop filter without changing anything else. This replacement results in a hybrid digital PLL (HDPLL). Both the original APLL and the designed HDPLL are Type I second-order systems. The real-time performance of the HDPLL and the receiver is provided and evaluated. Author

JPL/NASA is currently developing microspacecraft systems for future deep space applications. One of the frequency bands being investigated for microspacecraft is the Ka-band (32 GHz), which can be used with smaller equipment and provides a larger bandwidth. This article describes the successful development of a circularly polarized microstrip array with 28 dBic of gain at 32 GHz. This antenna, which is thin, flat, and small, can be surface-mounted onto the microspacecraft and, hence, takes very little volume and mass of the spacecraft. The challenges in developing this antenna are minimizing the microstrip antenna's insertion loss and maintaining a reasonable frequency bandwidth. Author

EFFECTS OF LOW SAMPLING RATE IN THE DIGITAL DATA-TRANSITION TRACKING LOOP
A. Mileant, S. Million, and S. Hinedi *In its* The Telecommunications and Data Acquisition Report 15 Feb. 1994 p 204-222 (For primary document see N94-29652 08-32)
(RTOP 314-40-41-11-06)
Avail: CASI HC A03/MF A03

This article describes the performance of the all-digital data-transition tracking loop (DTTL) with coherent and noncoherent sampling using nonlinear theory. The effects of few samples per symbol and of noncommensurate sampling and symbol rates are addressed and analyzed. Their impact on the probability density and variance of the phase error are quantified through computer simulations. It is shown that the performance of the all-digital DTTL approaches its analog counterpart when the sampling and symbol rates are noncommensurate (i.e., the number of samples per symbol is an irrational number). The loop signal-to-noise ratio (SNR) (inverse of phase error variance) degrades when the number of samples per symbol is an odd integer but degrades even further for even integers. Author

Conscan is commonly used by DSN antennas to allow adaptive tracking of a target whose position is not precisely known. This article describes an algorithm that is based on a Kalman filter and is proposed to replace the existing fast Fourier transform based (FFT-based) algorithm for conscan. Advantages of this algorithm include better pointing accuracy, continuous update information, and accommodation of missing data. Additionally, a strategy for adaptive selection of the conscan radius is proposed. The performance of the algorithm is illustrated through computer simulations and compared to the FFT algorithm. The results show that the Kalman filter algorithm is consistently superior. Author

(RTOP 314-30-61-02-10)
Avail: CASI HC A03/MF A03

This article presents an algorithm for estimating the signal-to-noise ratio (SNR) of signals that contain data on a downconverted suppressed carrier or the first harmonic of a square-wave subcarrier. This algorithm can be used to determine the performance of the full-spectrum combiner for the Galileo S-band (2.2- to 2.3-GHz) mission by measuring the input and output symbol SNR. A performance analysis of the algorithm shows that the estimator can estimate the complex symbol SNR using 10,000 symbols at a true symbol SNR of -5 dB with a mean of -4.9985 dB and a standard deviation of 0.2454 dB, and these analytical results are checked by simulations of 100 runs with a mean of -5.06 dB and a standard deviation of 0.2506 dB. It is often desirable to determine the potential for radio frequency interference between earth stations and orbiting spacecraft. This information can be used to select frequencies for radio systems to avoid interference or it can be used to determine if coordination between radio systems is necessary. A model is developed that will determine the statistics of interference between earth stations and elliptical orbiting spacecraft. The model uses orbital dynamics, detailed antenna patterns, and spectral characteristics to obtain accurate levels of interference at the victim receiver. The model is programmed into a computer simulation to obtain long-term statistics of interference. Two specific examples are shown to demonstrate the model. The first example is a simulation of interference from a fixed-satellite earth station to an orbiting scatterometer receiver. The second example is a simulation of interference from earth-exploration satellites to a deep-space earth station. Author (revised)

EXACT SPHERICAL WAVE SOLUTIONS TO MAXWELL'S EQUATIONS WITH APPLICATIONS Ph.D. Thesis
Guy G. Silvestri 1993 234 p
Avail: Univ. Microfilms Order No. DA9313926

Electromagnetic radiation from bounded sources represent an important class of physical problems that can be solved for exactly. However, available texts on this subject almost always resort to approximate solution techniques that not only obscure the essential features of the problem but also restrict application to limited ranges of observation. This dissertation presents exact solutions for this important class of problems and demonstrates how these solutions can be applied to situations of genuine physical interest, in particular, the design of device structures with prespecified emission characteristics. The strategy employed is to solve Maxwell's equations in the spherical coordinate system. In this system, fundamental parameters such as electric and magnetic multipole moments fall out quite naturally. Expressions for radiated power, force, and torque assume especially illuminating and simple forms when expressed in terms of these multipole moments. All solutions are derived ab initio using first-principles arguments exclusively. Two operator equations that receive particularly detailed treatment are the vector Helmholtz equation for the time-independent potential vector-a and the 'covariant divergence' equation for the energy-momentum-stress tensor T(exp mu nu). An application of classical formulas, as modified by the requirements of statistical mechanics, to the case of heated black bodies leads to inquiries into the foundations of quantum mechanics and their relation to classical field theory. An application of formulas to various emission structures (spherically shaped antennas, surface diffraction gratings, collimated beams) provides a basis upon which to characterize these structures in an exact sense and, ultimately, to elicit clues as to their optimum design. Dissert. Abstr.

A method for resolving range and Doppler target ambiguities when the target has substantial range or has a high relative velocity in which a first signal is generated and a second signal is also generated which is coherent with the first signal but at a slightly different frequency such that there exists a difference in frequency between these two signals of Delta f(sub t). The first and second signals are converted into a dual-frequency pulsed signal, amplified, and the dual-frequency pulsed signal is transmitted towards a target. A reflected dual-frequency signal is received from the target, amplified, and changed to an intermediate dual-frequency signal. The intermediate dual-frequency signal is amplified, with extracting of a shifted difference frequency Delta f(sub r) from the amplified intermediate dual-frequency signal done by a nonlinear detector. The final step is generating two quadrature signals from the difference frequency Delta f(sub t) and the shifted difference frequency Delta f(sub r) and processing the

two quadrature signals to determine range and Doppler information of the target. Official Gazette of the U.S. Patent and Trademark Office

Microstrip patch antennas offer considerable advantages in terms of weight, aerodynamic drag, cost, flexibility, and observables over more conventional protruding antennas. These flat patch antennas were first proposed over thirty years ago by Deschamps in the United States and Gutton and Baisinot in France. Such antennas have been analyzed and developed for planar as well as curved platforms. However, the methods used in these designs employ gross approximations, suffer from extreme computational burden, or require expensive physical experiments. The goal of this thesis is to develop accurate and efficient numerical modeling techniques which represent actual antenna structures mounted on curved surfaces with a high degree of fidelity. In this thesis, the finite element method is extended to cavity-backed conformal antenna arrays embedded in a circular, metallic, infinite cylinder. Both the boundary integral and absorbing boundary mesh closure conditions will be used for terminating the mesh. These two approaches will be contrasted and used to study the scattering and radiation behavior of several useful antenna configurations. An important feature of this study will be to examine the effect of curvature and cavity size on the scattering and radiation properties of wraparound conformal antenna arrays. Derived from text

RADAR RETURNS FROM A LOW-FLYING TARGET OVER A ROUGH SEA SURFACE UNDER MULTIPATH AND CLUTTER CONDITIONS Ph.D. Thesis
Feza Coskun 1992 137 p
Avail: Univ. Microfilms Order No. DA9313778

The scattering from surfaces plays an important role in radar operations when the radar beam intercepts the earth surface. Forward scattering gives rise to multipath phenomenon and backward scattering causes clutter returns. These two factors degrade the performance of a radar in its effort to detect a target. In this thesis, a computer simulation program, which traces the electromagnetic pulse in a controlled radar environment and enables us to observe the behavior of various field quantities at different locations, is developed. The program is capable of providing the statistical properties of various parameters such as electromagnetic field values, received voltage waveforms, and normalized radar cross section of the rough surface. It has a modular structure which ensures its flexibility for future extensions and changes. For the particular scenario set given in this thesis, the rough surface is chosen to be the sea surface, the radar antenna has a rectangular aperture, and the target is a flat perfectly conducting rectangular plate. A literature survey on rough surface scattering, multipath, and clutter shows that a single model which combines the effects of all levels of roughness of a surface does not exist. In this work, a composite sea surface model with two scales of roughness is developed. This model along with the antenna and target models is easy and efficient to implement on the computer. Various results on the electromagnetic field from the simulations of different scenarios are provided and compared. The simulation program is used to obtain the ambiguity function of the received time waveform. The received signals, which consist of the returns due to target, clutter, and multipath, are processed by the discrete cross ambiguity function routine and results on both coherent and incoherent processing are provided and discussed. Dissert. Abstr.

INTEGRAL EQUATION ANALYSIS OF COMPOSITE BODIES OF REVOLUTION AND ARBITRARY SURFACES WITH APPLICATION TO CAVITY-BACKED ANTENNAS Ph.D. Thesis
Timothy E. Durham 1992 165 p
Avail: Univ. Microfilms Order No. DA9311280

A formulation is developed to treat radiation from structures consisting of conducting and/or dielectric bodies of revolution (BOR) in the presence of multiple arbitrarily shaped three dimensional objects. A set of integral equations is developed on the surfaces of the combined structure using the electromagnetic boundary conditions. The resulting integro-differential equations are solved using the method of moments. On the BOR, harmonic entire domain expansion functions are used for the circumferential dependence, while overlapping subdomain functions are used to model the axial curvature. The arbitrarily shaped portions of the structure are modeled wing triangular surface patch basis functions. The resulting system matrix has a partial block diagonal nature which provides a more economical solution for structures which have some rotational symmetry. The accuracy of the BOR and arbitrary surface formulation is verified using several different approaches. The self-consistency method is used to verify the analysis for both perfectly conducting and dielectrically loaded structures. Special emphasis is placed on a unique cavity-backed antenna that is fed by large aperture patches. Numerical results are presented and compared to radiation pattern measurements performed on these antennas with very good agreement being obtained. An approach for solving the problem of junctions between bodies of revolution and arbitrary surfaces is investigated and shown to be accurate for some cases. Dissert. Abstr.

REMOTE OBSERVATORY ACCESS VIA THE ADVANCED COMMUNICATIONS TECHNOLOGY SATELLITE Ph.D. Thesis
Georghios Andreou Georghiou 1992 141 p
Avail: Univ. Microfilms Order No. DA9313729

The remote access of the Apache Point Observatory (APO) at Sunspot, New Mexico, by using the Advanced Communications Technology Satellite (ACTS) is investigated. This opportunity arose as a result of the announcement by NASA proposing investigations that demonstrate communications techniques and services and verifying technology implementations by using ACTS. An end-to-end simulation testbed has been developed for the underlying satellite communication network, which is composed of the APO's LAN, the remote observer's LAN, and part of the ACTS Low Burst Rate 2 (LBR-2) network which serves as the internetworking medium between the two LAN's. This is accomplished by using COMNET II.5, a communication network oriented tool for designing, developing, and executing simulations within one user interface. Performance tests at different network elements have been performed to measure processing delays. Specifications and/or salient features of network functional subsystems have been used to reach a high degree of accuracy with the real model. Additional features taken into consideration are the traffic model of the telescope, the TDMA frame structure, and the potential protocols for end-to-end delivery of data. Based on the testbed, a detailed output report determines factors in the network, such as access possibilities between APO and major astronomical centers and observatories using the ACTS; latency between the APO and the remote user; TDMA frame capacity requirements to support network data under various conditions; buffer sizes required in various network elements to support data transfer; optimum protocol configurations for end-to-end transport; potential ACTS terminal limitations on the data transport process; identify bottleneck areas and conditions under which they occur in optimizing such a network; and potentials for growth in the APO data source capacity, using the ACTS-type of frame structure. Dissert. Abstr.

ADAPTIVE POWER CONTROL AS A FADE COUNTERMEASURE ON SATELLITE LINKS Ph.D. Thesis
Dennis Givens Sweeney 1993 169 p
Avail: Univ. Microfilms Order No. DA9312882

Satellite systems in the 20/30 GHz band are very susceptible to outages due to rain-induced fades. In order to reduce the impact of these fades, it has been proposed that the power of the uplink station transmitter be adjusted during the fade to compensate. This dissertation will explore some of the issues involved in implementing this uplink power control (ULPC). Fade slope is examined as a parameter to predict signal strength during a fade. A fade slope model based on fade physics is presented, but it strongly suggests that fade slope is not an appropriate parameter for ULPC. Real time scaling of attenuation from the downlink to the uplink shows more promise for ULPC. Differences in drop size distributions during a rain storm will result is different scaling factors. If the downlink attenuation

is limited to 6 dB at 20 GHz, real time scaling can be accomplished. A scaling type ULPC algorithm driven by downlink attenuation is tested on 66 hours of OLYMPUS 20/30 GHZ fade data. A similar algorithm driven by uplink attenuation is tested and the performance of the two algorithms is presented and compared. Dissert. Abstr.

Inspection of high-value structures, like bridges and buildings, using Ground Penetrating Radar (GPR) is an application of a technology that is growing in importance. In a typical inspection application, inspectors use GPR to locate structural components, like embedded reinforcing bars, to avoid weakening the structure while collecting core samples for detailed inspection. Advanced GPR, integrated with imaging technologies for use as an NDE tool, can provide the capability to quickly locate and characterize construction flaws and wear- or age-induced damage in these structures without resorting to destructive methods. In this paper, we discuss an important inspection application, namely, concrete bridge deck inspection. We describe an advanced bridge deck inspection system concept (Ground Penetrating Imaging Radar, GPIR) and present results from experiments designed to simulate the concept. DOE

PARTIALLY COHERENT DETECTION OF PSK SIGNALS IN RICIAN CHANNELS M.S. Thesis
Yasar Tunca 1992 113 p
(ISBN-0-315-85799-4; CTN-94-61167) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Channel models are developed for noisy phase reference and Rician fading channels, and all the assumptions in the models are explained. After a description of phase shift keying (PSK) signals, their coherent, differential, and multidifferential detection is explained. Analytical expressions are provided for their performance in additive white Gaussian noise and Rician channels. Bit error curves obtained by simulations are plotted and compared with the curves given in the literature. Assuming that partially coherent detection could be an alternative, metric expressions are derived for partially coherent detection of signals in general and applied to PSK signals. The bit error rate performance of partially coherent detection of uncoded binary and quaternary PSK signals obtained through simulation is presented for different signal to noise ratios of carrier recovery loop and direct component power to diffuse component power ratios. The performances obtained are compared to coherent and differential detection performances under the same conditions. Partially coherent detection showed no significant improvement compared to multidifferential detection. It is suggested that partially coherent detection will give significant improvements compared to differential detection for coded systems.

INVESTIGATIONS OF DISPERSION CHARACTERISTICS OF MICROWAVE/OPTICAL GUIDED WAVE STRUCTURES BY USING TRANSMISSION LINE MATRIX METHOD M.S. Thesis
Bing Qiu 1993 123 p
(ISBN-0-315-85856-7; CTN-94-61170) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A new three dimensional space (3D) condensed node transmission line matrix (TLM) algorithm is presented for the analysis of dispersion characteristics of microwave and optical guided wave structures. The new algorithm requires much less computer memory and computation time than the conventional 3D condensed node TLM. The application of the new algorithm to the modeling of inhomogeneous, lossy, and unbounded guided structures is investigated. More specifically, techniques such as variable mesh size and absorbing boundary conditions are introduced in the algorithm. The error sources, effects due to excitation, and output point location are analyzed, and suggestions are made for more efficient and accurate modeling of complicated geometries. In particular, special treatment is implemented to model curved boundaries accurately. Finally, the dispersion characteristics of various kinds of rectangular and circular guided structures are calculated using the new algorithm. It is found that the results obtained agree fairly well with those observed by theoretical or other proved numerical methods. Author (CISTI)

The propagation of an electron wave along the length of two coupled quantum wires is investigated theoretically. The quantum nature of the wires arises due to the smallness of their cross sectional area, which is usually of the order of 100 Angstroms in any direction. The wires are defined in terms of two quantum wells such that the electron motion is restricted in the direction transverse to the length of the wire and unrestricted along its length. It is assumed that the wires are sufficiently close to each other that an electron wave introduced in one of the wires is able to tunnel itself into the other. In fact, the wave could oscillate back and forth between the wires at a frequency dependent on the width and depth of the quantum wells and the distance separating the wires. The frequency would also be affected by the effective mass of the electron. It is shown that the motion of the electrons in the parallel and perpendicular directions becomes coupled and that the frequency of oscillations of the electron wave depends on the motion of the wave parallel to the wire. The frequency and the stationary state wave functions for an electron bound to two quantum wires is derived using an approach based on the time dependence of the probability amplitudes of occupancy for the electrons in one wire or the other. Numerical results are obtained and discussed. CISTI

COMMUNICATIONS TECHNOLOGY FOR UNATTENDED SENSORS
D. A. Fuess, D. W. Myers, D. M. Benzel, and J. Baker Aug. 1993 32 p
(Contract W-7405-eng-48)
(DE94-005685; UCRL-ID-114079) Avail: CASI HC A03/MF A01

The objective was to design and demonstrate proof-of-concept communication subsystems for use in unattended sensors. These designs investigated current, advanced technology for frequency synthesis and control, and the use of commercial, highly integrated radio frequency components. The three following subsystems were evaluated: (1) a synthesized (225-400 MHz) exciter/transmitter, (2) a wideband, 100-W, radio-frequency power amplifier (for boosting the level of the exciter/transmitter output), and (3) a command receiver operating in the 240-270 MHz satellite communication band. These subsystems were integrated into a prototype sensor system. Software was written using the Lawrence Livermore National Laboratory's Modular Intelligent Sensor System (MISS) specification for microprocessor control of these communication elements. Operation of the sensor system using these subsystems was demonstrated. DOE

Polarimetric AIRSAR data of July 13, 1990 acquired over Mahatango watershed area was processed for the identification of corn fields and forested areas. Polarization Phase Difference (PPD) values were computed for the corn fields at P-, L- and C- bands and studied as a function of frequency. The results compare well with the model calculations at 24 deg. incidence angle where as the locations of corn fields were computed to be at 35 deg. incidence angle. The discrepancy is attributed to lack of accurate ground truth and the undulating topography of the corn fields. Another study reported here deals with the usefulness of Polarization Index (PI) for the study of vegetation. PI was found to be dependent on frequency for corn fields where as for forest trees no such dependence was noticed. PI(sub HH,HV) is more useful parameter compared to PI(sub HH,VV) even for the study of corn fields. DOE

THREE-DIMENSIONAL EFFECTS FOR RADIO FREQUENCY ANTENNA MODELING
M. D. Carter, D. B. Batchelor, and D. C. Stallings Sep. 1993 36 p
(Contract DE-AC05-84OR-21400)
(DE94-006102; ORNL/TM-12464) Avail: CASI HC A03/MF A01

Electromagnetic field calculations for radio frequency (RF) antennas in two dimensions (2-D) neglect finite antenna length effects as well as the feeders leading to the main current strap. Comparisons with experiments indicate that these 2-D calculations can overestimate the loading of the antenna and fail to give the correct reactive behavior. To study the validity of the 2-D approximation, the Multiple Antenna Implementation System (MAntIS) has been used to perform 3-D modeling of the power spectrum, plasma loading, and inductance for a relevant loop antenna design. Effects on antenna performance caused by feeders to the main current strap, conducting sidewalls, and finite phase velocity are considered. The plasma impedance matrix for the loading calculation is generated by use of the ORION-1D code. The 3-D model is benchmarked with the 2-D model in the 2-D limit. For finite-length antennas, inductance calculations are found to be in much more reasonable agreement with experiments for 3-D modeling than for the 2-D estimates. The modeling shows that the feeders affect the launched power spectrum in an indirect way by forcing the driven RF current to return in the antenna sidewalls rather than in the plasma as in the 2-D model. Thus, the feeders have much more influence than the plasma on the currents that return in the sidewall. It has also been found that poloidal dependencies in the plasma impedance matrix can reduce the loading from that predicted in the 2-D model. For some plasma parameters, the combined 3-D effects can lead to a reduction in the predicted loading by as much as a factor of 2 from that given by the 2-D model. DOE

A PHYSICAL OPTICS MODEL FOR SCATTERING OF HF RADIATION BY IRREGULAR TERRAIN
G. J. Burke Jan. 1994 8 p Presented at the 10th Annual Review of Progress in Applied Computational Electromagnetics, Monterey, CA, 21-26 Mar. 1994
(Contract W-7405-eng-48)
(DE94-006187; UCRL-JC-115241; CONF-940366-1) Avail: CASI HC A02/MF A01

Physical optics models were developed for scattering of HF radiation by irregular terrain when an antenna is located on or near the scattering surface. The primary interest was in skywave radiation patterns for communication links using the ionosphere. Second-order reflections were included in the solution through an image approximation, and the UTD result for an impedance half-plane was used to reduce reflections due to truncating the current distribution on the surface. Arbitrary 2-D or 3-D terrain profiles can be entered into the codes, and the source can be an antenna with currents generated by the NEC method-of-moments code or a point source. Results were validated by comparing with 2-D integral equation solutions for actual terrain contours. DOE

Pulse compression is a technique which allows improvement in detecting radar targets while preserving a good resolution power at a distance. This technique consists in transmitting a longer coded pulse and receiving it with a filter adapted to the code transmitted. Digital systems of pulse compression can possess a wider variety of codes than analog systems and can use a new code at each transmission. These two advantages are combined to reduce radar noise. The performance of digital pulse compression is evaluated for different types of radar interference. To counter certain types of interference such as replication of code, it is necessary to use a new code at each transmission. Two types of codes are studied: biphase pseudorandom codes and polyphase codes derived from linear frequency modulated signals or chirp. Supplementary methods, such as cumulative detection and coherent integration of a salvo of pulses, are sometimes needed to supress interference residuals. Digital pulse compression was also applied in real time and the results are supported by computer simulations and by tests on an experimental prototype. CISTI

EVALUATION OF DUAL POLARIZATION ATTENUATION OF MILLIMETER FREQUENCIES THROUGH A METEOROLOGICAL RADAR

D. Giuli, L. Baldini, L. Facheris, and P. Mazzetti *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 9 p (For primary document see N94-30495 08-32)

Copyright Avail: CASI HC A02/MF A03

The possibility of exploiting measurements obtained through a C-band dual polarization radar is examined, as an auxiliary tool for the planning of radio relays operating at millimeter frequencies. C-band weather radars, though featuring several advantages related to their cost and reduced size, provide partially attenuated rainfall measurements with respect to their S-band counterparts. However, good reliability of rainfall rates based on C-band dual polarization measurements is achieved after proper processing based on iterative procedures for propagation attenuation due to rain. A simulation program has been utilized to provide synthetic rainfall and C-band dual polarization reflectivity data related to several storms, corresponding to different meteorological conditions. Simulated data, after proper correction of radar data, have been utilized to evaluate path attenuation statistics useful to predict fading at millimeter frequencies and related outage probability. Results show that a C-band radar can be profitably exploited for the purpose, prediction being feasible under different space-time rain patterns. On the other hand, the analysis has shown that differential reflectivity is not so essential for the aforementioned purpose as absolute reflectivity, even if it could be utilized with success in real contexts for the identification of hydrometeors (hail, graupels, wet snow) other than rain, which may be responsible for more pronounced scattering and absorption phenomena. PROPAGATION MODELING OF MOIST AIR AND SUSPENDED WATER/ICE PARTICLES AT FREQUENCIES BELOW 1000 GHz

H. J. Liebe, G. A. Hufford, and M. G. Cotton *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 11 p (For primary document see N94-30495 08-32)

Copyright Avail: CASI HC A03/MF A03

Propagation characteristics of the atmosphere are modeled for the frequency range from 1 to 1000 GHz (1 THz) by the modular millimeter-wave propagation model MPM. Refractivity spectra of the main natural absorbers (i.e., oxygen, water-vapor, suspended droplets and ice particles) are computed from known meteorological variables. The primary contributions of dry air come from 44 O2 lines. Results from extensive 60-GHz laboratory measurements of the pressure-broadened O3 spectrum were applied to update the line data base. The water-vapor module considers 34 local H2O lines plus continuum contributions from the H2O spectrum above 1 THz, which are formulated as wing response of a pseudo-line centered at 1.8 THz Cloud/fog effects are treated with the Rayleigh approximation employing revised formulations for the permittivities of water and ice. The influence of the Earth's magnetic field on O2 absorption line becomes noticeable at altitudes between 30 and 120 km. Anisotropic medium properties result, which are computed by the Zeema propagation model ZPM. Here the elements of a complex refractivity tensor are determined in the vicinity (plus or minus 10 MHz) of O2 line centers and their effect on the propagation of plane, polarized radiowaves is evaluated. A spherically stratified (0-130 km) atmosphere provides the input for the codes MPM and ZPM in order to analyze transmission and emission properties of radio paths. Height profiles of air and water vapor densities and of the geocoded magnetic field are specified. ZPM predicts polarization- and direction-dependent propagation through the mesosphere. Emission spectra of the 9+ line (61150 plus or minus 3 MHz) for paths with tangential heights ranging from 30 to 125 km are consistent with data measured by the shuttle-based millimeter-wave limb sounder MAS. THE INFLUENCE OF THE EVAPORATION DUCT ON THE ANGLE OF ARRIVAL AND AMPLITUDE OF THE BACKSCATTERED SIGNAL FROM TARGETS LOW ABOVE THE SEA

H. Sittrop, H. Gravesteijn, and H. J. M. Heemskerk *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 13 p (For primary document see N94-30495 08-32)

Copyright Avail: CASI HC A03/MF A03

The impact of multipath and atmospheric refractions on the amplitude,

the apparent Radar Cross Section, RCS(sub a), and the Angle of Arrival, AOA, of low altitude target radar backscatter at 9.4 GHz, can be described as typical for 3 ranges, and 3 duct height intervals, i.e., respectively 6, 10, and 19 km, and 10 m, 10-18 m and 18-26 m. The targets are tri-hedrals mounted on poles injected into the sea-bed at the above mentioned ranges. Sensor height is 23 m above normal low sea-tide and the target heights vary from 4.5 m to 8 m depending on the sea-tide. Whereas the RCS(sub a) and the AOA show opposite behavior at 10 km and at 19 km, i.e. and RCS(sub a) decrease and an AOA decrease at 10 km, both for duct heights of 18-26 m, the opposite occurs for duct heights of 10-18 m. However, in this latter case no dramatic differences occur with respect to the AOA. At the 6 km range the RCS(sub a) is persistently larger (4-8 dB) than the free-space RCS(sub o), for duct heights less than 10 m, whereas the AOA is predominantly negative for all recorded duct heights (0-26 m). On the other hand the RCS(sub a) at this range reduces from circa +6 dB to -6 dB relative to RCS(sub 0) for increasing target height and duct heights of 10-26 m. This characteristics target/duct height behavior may introduce misleading information about the type of target. Particularly at long ranges (19 km) and target heights of circa 6 m, the RCS(sub a) may be -20 dB with respect to the free-space RCS(sub o), and the AOA +.6, for duct heights of 10-26 m. Detection probability reduces significantly, and if the target is detected, the height position is entirely wrong, i.e. circa +200 m, whereas the target is only 6 m above sea. At duct heights between 10-18 m the RCS(sub a), and hence the detection probability increases at 19 km. On the other hand this RCS(sub a) can be 10-20 dB lower at 10 km, particularly at target heights between 4-6 m. A lost tract at 10 km may therefore be possible, if detection was just feasible at 19 km at these duct heights. PCPEM predictions and measurements at 5.8 km show in general a fairly comparable trend for target heights between 6-7 m, however, for duct heights of 0-18 m, a too high RCS(sub a) is predicted and for the observed duct heights of 18-25 m a too low RCS(sub a). Within the region of transition from a too high to a too low prediction, comparable values are observed. For target heights between 5.5-6 m PCPEM predicts too large values for all duct heights. A fog system capable of producing water droplets with diameters between 5 and 40 micrometers was used for multispectral transmittance measurements. Measurements were conducted at an arid, desert field location on the White Sands Missile Range, New Mexico. The fog system consists of a supply of local tap water, 50 gallon holding barrels, high pressure hoses and connectors, and an array of specially designed spray nozzles. The spray nozzles have precision made .006-inch diameter orifices. Water under 1000 psi of pressure is forced through the small orifice and impacts onto a curved metal pin causing droplet formation and dispersion. Droplet size distribution of the man-made fog were measured by forward scattering particle-measuring instruments. The advantages of using the fog generation system are low energy requirements, high rates of droplet production, environmentally safe dispersion, and commercial availability. Transmittance measurements were taken by a Multi-Path Transmissometer/Radiometer (MPTR). The MPTR is capable of obtaining transmittances at .4-.7 micron, 1.0-1.1 micron, 3.5-4.8 micron, and 7.9-12.3 micron spectral bands. Results will be presented on transmittance comparisons between the different wavelength bands during varying fog density conditions. The transmittance data from the line of sight were tested for optical depth linearity in the various wavelength bands. Author

Transmittance in the visible and thermal infrared may be estimated from a variety of in-situ and remote techniques using ground-based or airborne sensors. However, estimation of transmittance in the troposphere from data gathered by sensors on space platforms remains a problem, especially over land surfaces. This paper presents two preliminary methods: one to compute visibility using changes in contrast from a series of luminance images or measuring changes in the nonzero frequency amplitudes from the associated frequency domain images, and the other to calculate thermal infrared transmittance over a horizontal, vertical, or slant path that uses estimates of precipitable water from satellite data, combined with sounding data from satellite or other sources. AN EXPERIMENTAL AND COMPREHENSIVE METHOD TO MEASURE EMISSION CHARACTERISTICS [UNE METHODE EXPERIMENTALE ET GLOBALE DE MESURE DE L'EMISSIVITE]

R. Marchal *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 8 p In FRENCH; In FRENCH (For primary document see N94-30495 08-32)

The characteristics of emission may be of thermal infrared multispectral processes: either through direct measurements on the emitted flux, which are compared to a reference black body, or through measurements on reflectivity and application of the Kirchoff laws. Both approaches have advantages and drawbacks according to the type of emission characteristics that are studied. The method which is used in this study uses the first principle: it concerns itself with relatively high levels of emissions (greater than 0.5), which are directional and controlled by a given sensor. In order to maximize the precision of measurements, testing respects the following conditions: (1) lessening of residual parasite flux, through the use of low emission materials and a cooled diaphragm, thus creating a confined enclosure; (2) taking into account the residual parasite flux, through models of radiation exchange within the enclosure; (3) assessment of the homogeneity in temperature of both the sample and the reference materials; and (4) calculations on the confidence levels, in function of the variances in the beginning parameters. This use of models, added to technical advances, make it possible to build a very inexpensive test site, at least as far as specific purchases were concerned. Several comparative measurements showed that the range of measurable emissions goes from 0.5 to 1, with an absolute confidence level of 0.05 to 0.02, according to the material. The best performance was obtained when highly emissive and highly heat conductive materials were used. Transl. by FLS

EXPERIMENTAL EVALUATION OF CAMOUFLAGE EFFECTIVENESS IN THE THERMAL INFRARED **c74**

Pieter A. M. Jacobs *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 12 p (For primary document see N94-30495 08-32)

Copyright Avail: CASI HC A03/MF A03

The detectability of a target in the infrared spectral region is determined by differences between the radiative signatures of the target and the local background. This implies that both, the difference in surface temperature and emissivity Delta T resp. Delta epsilon and the distribution of these differences over the target area and the background, are of major importance. Therefore camouflage measures have to address both issues in order to achieve maximum signature adaptation to the background. To determine the ability of a camouflage material to follow temperature changes in the background, measurements of camouflage and background temperatures have to be performed under a variety of meteorological conditions. Measurements of representative weather and background conditions are needed to determine those situations, where the camouflage material effectively reduces the target signature. The degree of temperature reduction depends on the required level of protection, that is for detection, recognition and identification. Statistical analyses are given for various camouflage materials in relation to a number of background elements. Camouflage effectiveness is expressed in the percentage of time for which the apparent

temperature contrast between the camouflage material and a background element is 1, 2 or 5 C. Analyses are performed for five consecutive weeks of measurements in summer and winter, using data which were taken during a measurement campaign at Gilze Rijen air force base in 1990.

During 1993, Canada, France, Germany and the United Kingdom will be participating in the Smoke and Obscurants Countermeasures Materials Evaluation Tests (SOCMET). The tests will be carried out under the auspices of the NATO Army Armaments Group, AC/225, Panel VI, Sub-Panel 7 whose interests include multispectral smoke screening systems. The tests will comprise two sets of trials; one under cold climate conditions in Quebec, Canada, during February/March 1993 and the other in temperate conditions in Bourges, France during September 1993. This paper provides an insight into the management and aims of SOCMET. The evaluations will be seeking to identify candidate materials which create effective obscurant screens in the visible, infrared and millimetric bands of the electromagnetic spectrum. These materials will be disseminated through a range area dispersal. A key element of the trials will be the evaluation of field test instrumentation which may eventually lead to the development of standardized evaluation techniques. Following the trials, a scientific workshop will be held to review the results. A final report will be presented to NATO which will form the basis of future collaborative developments on multispectral screening systems leading towards standard NATO documentation on smoke and obscurant systems.

GLOBAL APPROACH TOWARDS THE EVALUATION OF THERMAL INFRARED COUNTERMEASURES **c74**
Patrick Verlinde and Philippe Wilms *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 8 p (For primary document see N94-30495 08-32)
Copyright Avail: CASI HC A02/MF A03

This paper proposes a procedure for the numerical evaluation of the efficiency of countermeasures in the thermal infrared. This procedure consists of three phases. In the first phase the characteristics of different thermal camouflage materials are tested on a lab-scale. These tests comprise measurements of the attenuation of the incident infrared energy and/or of the thermal emissivity factor. With respect to the attenuation measurement, a calibrated infrared sensor is used, to determine the radiation patterns of an object. The comparison of these patterns before and after the application of a camouflage system, gives an absolute measure of its attenuation. The result of this measurement is important since the attenuation is closely related to the contrast between the camouflaged object and its background and thus to the probability of detection. Contrast however, is not the only important feature for the detection of an object in a thermal image. That is why in a second phase the countermeasures under evaluation are tested in a real environment. During this phase, a numerical value is given to the efficiency of the considered camouflage in the thermal infrared, using features selected from those which are known to be important for human vision. These include, besides contrast, other features such as correlation and texture. The third and final phase aims at a verification and a validation of the test results. Indeed, it is of crucial importance to find a link between the performance obtained in the field and the characteristics measured on a lab-scale. It is also necessary to verify that a good correlation exists between the efficiency as determined by human observers and the result of this numerical evaluation procedure. This will be done using a database of thermal images taken with a GEC Avionics TICM II (8 to 12 micron). Those images are then presented as well to human observers as to the machine in a project called 'Psychotest'.

This paper provides an unclassified overview of the U.S. Army program that collects and disseminates information about the effects of battlefied smokes and obscurants on weapon system performance. The primary mechanism for collecting field data is an annual exercise called SMOKE WEEK. In SMOKE WEEK testing, a complete characterization is made of the ambient test conditions, of the electromagnetic radiation propagation in clear and obscured conditions, and of the obscuring cloud that the particles that comprise the cloud. This paper describes the instrumentation and methodology employed to make these field measurements, methods of analysis, and some typical results. The effects of these realistic battlefield environments on weapons system performance are discussed generically.

INFRARED POLARIZATION SIGNATURES
D. L. Jordan and G. Lewis *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 6 p (For primary document see N94-30495 08-32)
Copyright Avail: CASI HC A02/MF A03

Target detection using passive electro-optic devices operating in the 8 to 14 micron band is often limited by background clutter. A possible method of overcoming this limitation may be to use the polarization content of the image to discriminate between man-made targets and natural background. Laboratory measurements are presented of the polarization state of 10 to 6 micron radiation reflected from, and emitted by, a range of materials. It is concluded that elliptical polarization is not of primary importance and that measurements of the degree of linear polarization appear to provide useful discrimination between man-made objects and 'natural' ones.

In order to assess very accurately the performances of millimeter wave imaging passive systems, efforts have been made towards the development of a straightforward easy to use computer code. This simulation model has been used to evaluate the influence of meteorological conditions on radiometric contrasts. The following parameters are studied: frequency, terrain emissivity, and radiometer position. A first set of simulations is done in the scatter-free atmosphere assumption. Then scattering by hydrometeors is taken into account. In each case, ground surface discrimination by their radiometric temperature is discussed.

Error probabilities are calculated for the detection of a target illuminated through a random medium in the presence of ambient noise. Comparisons are made between monostatic operation, in which double passage of the radiation leads to an enhanced amplitude and fluctuation of the received

signal, and bistatic operation, where the outward and return radiation paths traverse uncorrelated regions of the intervening random medium. It is shown that although common transmit/receive optics are advantageous in the case of low signal to noise ratios, in normal regimes of operation a bistatic arrangement leads to lower total error probability, particularly when the scattering medium generates strong scintillation in the target plane.

During the last four years, the Microwave Remote Sensing Laboratory of the University of Massachusetts has studied the polarimetric backscatter response of natural and man-made surfaces at 35, 95, and 225 GHz. These surfaces include grass, asphalt, snowcover, and trees. In addition, ground-based and airborne backscatter measurements of clouds and precipitation were made at 95 GHz. The results of these experiments are summarized by presenting histograms of normalized radar cross section for trees, snowcover, and clouds. The temporal dependence of the normalized radar cross section for snowcover is also presented for 95 and 225 GHz which shows a strong diurnal variation due to melting and refreezing. Also presented is the angular dependence of backscatter from grass and asphalt at 35, 95, and 225 GHz, as well as volume backscattering coefficients for airborne measurements of clouds and precipitation at 96 GHz.

A HYBRID ELECTROMAGNETIC-STATISTICAL APPROACH FOR CHARACTERIZING MMW SCATTERING BY TERRAIN
Fawwaz T. Ulaby, Paul Siqueira, and Kamal Sarabandi *In* AGARD, Atmospheric Propagation Effects Through Natural and Man-Made Obscurants for Visible to MM-Wave Radiation Nov. 1993 8 p (For primary document see N94-30495 08-32)

The performance of millimeter wave (MMW) radar systems in target detection, navigation, and other applications depends in part on the scattering characteristics of the terrain background. Two different approaches have been pursued in the literature for characterizing MMW scattering by terrain. The first approach relies on the development of electromagnetic scattering models that relate the backscattering coefficient sigma of a given terrain type (such as bare ground surfaces, snow cover, and vegetation) to the physical properties of the terrain target, and then verifying model predictions though experimental observations conducted under semicontrolled field conditions. The second approach is entirely empirical in nature; it relies on the acquisition of extensive radar data from which statistical distributions are generated. This paper provides an overview of how the hybrid approach can be used to simulate the statistical properties of terrain backscatter at millimeter wavelengths for several types of terrain, including bare soil surfaces, vegetation, and snow cover. The hybrid approach incorporates scintillation effects associated with coherent sensors together with information about the mix of terrain categories present in the scene. Two types of input data (or a merged set of both) can be used as input to the clutter simulation package: measured data that is available in a University of Michigan data base or data generated by electromagnetic models. The data base is available as a handbook that contains MMW scattering observations reported in the literature for certain terrain types and conditions. Alternatively, a set of electromagnetic models can be used for calculating the backscattering coefficient sigma of the specified terrain type. These models, which are semiempirical in form, are based on highly complicated theoretical models that had been tested against experimental observations. With this approach, it is possible to generate a probability density function for the backscatter from a certain type of terrain without the need for a measured clutter data base. This is particularly attractive at millimeter wavelengths because only a limited amount of terrain clutter data is currently available.

The principle of granulometry through particle light diffusion in environments with very low levels of concentration was studied. A model was built and its response, when particles were randomly distributed in the measured volume, was numerically simulated. Atmospheric, urban, rural, and seaside conditions were used in models with extended ranges of concentration. Several wavelengths of light were tested. Atmospheric aerosol granulometry is feasible if the concentration per volume is greater than or equal to 10(exp -5) ppm, and if the light wavelength is of the same order as the average size of the particles. The particles' contribution to atmospheric visibility may be measured if a preliminary calibration of the detection system is put into place. Laboratory equipment was used to validate the use of models. In order to simulate the appropriate particles' concentration, a 10 dm(exp 3) test chamber was built. Experiments, conducted with licopode powder (25 to 35 micron in diameter) in known concentration per volume, were correctly reproduced.

Radar cross section (RCS) measurements were made on an extensively instrumented ground-clutter patch over a period of one month from late summer to early fall. The instrumentation allowed collection of a full set of data on meteorological conditions, solar flux, and soil moisture content. The RCS measurements were made using a 95-GHz, polarimetric, monopulse instrumentation radar. The radar is all solid-state, coherent, frequency steppable over a 640-MHz bandwidth, and completely polarimetric for linearly or circularly polarized radiation. The clutter area measured was located in Grayling, Michigan, and consisted of a rectangular patch of ground, 50 by 100 m in area, at a range of about 100 to 250 m from the radar. The clutter patch included areas of bare sandy ground, short grass, low shrubs, evergreen trees, and deciduous trees and was similar to a NATO European environment. A wide range of atmospheric conditions were observed over the measurement period, including a few days of measurable snowfall. The paper describes analysis of the effects of different clutter types and different atmospheric conditions on the measured RCS of the clutter patch.

The fuzzy logic theory is used to derive knowledge combination rules for heuristic search algorithms and data fusion problems. Heuristic search algorithms are especially designed for expert systems which have to explore a large solution space in a limited amount of time. Therefore, search algorithms using heuristic knowledge are designed to limit the exploration of the solution space while preserving some quality in the results. An automatic target recognition expert system was designed using this approach. However, the fuzzy logic approach could be applied to other types of expert systems and to data fusion problems.

The problem of leader election in distributed systems is considered in a dynamic context where processes may participate and crash spontaneously. Processes communicate by means of buffered broadcasting as opposed to usual point to point communication. A leader election protocol in such a dynamic system is designed. As the problem at hand is considerably complex, a step wise refinement design method starting from a simple leader election protocol is adopted. In a first refinement a symmetric solution is obtained and eventually a fault tolerant protocol is constructed. This gives rise to three protocols. The worst case message complexity of all protocols is analyzed. A formal approach to the verification of the leader election protocols is adopted. The requirements are specified in a property oriented way and the protocols are denoted by means of extended finite state machines. It is proven using linear time temporal logic that the protocols satisfy their requirements. The protocols are specified in more detail in the process algebra formalism ACP (Algebra of Communicating Processes). ESA

New challenges in high performance computing and communications are driving the need for fast, geographically distributed networks. Applications such as modeling physical phenomena, interactive visualization, large data set transfers, and distributed supercomputing require high performance networking (St89)(Ra92)(Ca92). One measure of a communication network's performance is the time it takes to complete a task -- such as transferring a data file or displaying a graphics image on a remote monitor. Throughput, defined as the ratio of the number of useful data bits transmitted per the time required to transmit those bits, is a useful gauge of how well a communication system meets this performance measure. This paper develops and describes an analytical model of throughput. The model is a tool network designers can use to predict network throughput. It also provides insight into those parts of the network that act as a performance bottleneck. DOE

FREQUENCY-DOMAIN ANALYSIS OF NONLINEAR MICROWAVE CIRCUITS Ph.D. Thesis
T. Naerhi Jun. 1993 148 p
(PB94-132024; VTT/PUB-148; ISBN-951-38-4386-6) Copyright Avail: CASI HC A07/MF A02

A frequency-domain method is presented for the numerical steady-state analysis of nonlinear microwave circuits. Nonlinear elements are described with Chebyshev expansions or rational functions of Chebyshev expansions and their response is calculated directly in the frequency domain. Since no time-to-frequency conversions are needed, the method is especially suitable for multi-tone problems which are difficult to solve with harmonic-balance methods. Numerically stable recursive procedures allow the use of high-degree expansions for strongly nonlinear devices. The analysis method is coupled with a new measurement-based modeling approach, where the frequency-domain large-signal model is directly constructed through integration from the measured small-signal y-parameters. The resulting model is inherently consistent and allows an accurate representation of the frequency-dependent characteristics of nonlinear devices. The analysis method and modeling approach are experimentally verified by two- and three-tone measurements on a MESFET mixer. NTIS

Development of useful high-critical-temperature superconductors requires synthesis of superconducting compounds; fabrication of wires, tapes, and films from these compounds; production of composite structures that incorporate stabilizers or insulators; and design and testing of efficient components. This report describes technical progress of research and development efforts aimed at producing superconducting components in the Y-Ba-Cu, (Bi,Pb)-Sr-Ca-Cu, (Tl,Pb, Bi)-(Ba,Sr)-Ca-Cu, and Hg-Ba-Ca-Cu-O oxide systems. Topics discussed are synthesis and heat treatment of high-T(sub c) superconductors; formation of monolithic and composite wires, tapes, and coils, characterization of structures and superconducting and mechanical properties; fabrication and properties of films; and development of properties of films; and development of prototype components. Collaborations with industry and academia are documented. DOE

(NASA-CR-195241; NAS 1.26:195241) Avail: CASI HC A04/MF A01

The cooperative agreement partly supported research leading to the open-literature publication cited. Additional efforts under the agreement included research into fault modeling of semiconductor devices. Results of this research are presented in this report which is summarized in the following paragraphs. As a result of the cited research, it appears that semiconductor failure mechanism data is abundant but of little use in developing pin-level device models. Failure mode data on the other hand does exist but is too sparse to be of any statistical use in developing fault models. What is significant in the failure mode data is that, unlike classical logic, MSI and LSI devices do exhibit more than 'stuck-at' and open/short failure modes. Specifically they are dominated by parametric failures and functional anomalies that can include intermittent faults and multiple-pin failures. The report discusses methods of developing composite pin-level models based on extrapolation of semiconductor device failure mechanisms, failure modes, results of temperature stress testing and functional modeling. Limitations of this model particularly with regard to determination of fault detection coverage and latency time measurement are discussed. Indicated research directions are presented. FABRICATION ISSUES IN OPTIMIZING YBa(2)Cu(3)O(7-x) FLUX TRANSFORMERS FOR LOW I/f NOISE
F. Ludwig, E. Dantsker, D. T. Nemeth, D. Koelle, A. H. Miklich, J. Clarke, S. Knappe, H. Koch, and R. E. Thomson Nov. 1993 15 p Presented at the International Superconductive Electronic Conference, Boulder, CO, 11-14 Aug. 1993
(Contract DE-AC03-76SF-00098)
(DE94-005209; LBL-34878; CONF-930863-3) Avail: CASI HC A03/MF A01

We describe an improved interconnect technology for the fabrication of multiturn flux transformers from YBa(2)Cu(3)O(7-x) - SrTiO(3) - YBa(2)Cu(3)O(7-x) multilayers. The essential improvements are reductions in the thicknesses of the trilayer films, typically to 100 nm 250 nm and 250 mn respectively, and in the deposition rate, to 0.07 nm/laser pulse. This process yields crossovers in which the critical current density in the upper YBa(2)Cu(3)O(7-x) film at 77 K is (2-3) x 10(sup 6) A cm(sup -2). In situ trilayers exhibited 1/f flux noise levels at I Hz below the measurement sensitivity of 15(mu)Phi(sub 0) Hz(sup -1/2), where Phi(sub 0) is the flux quantum. However, the flux noise of trilayers in which each layer had been patterned was significantly higher. The best flip-chip magnetometer had a white noise of 40 fT Hz(sup -1/2) increasing to 340 fT Hz(sup -1/2) at I Hz; the corresponding flux noise levels were 9 (mu)Phi(sub 0) Hz(sup -I/2) and 75 (mu)Phi(sub 0) Hz(sup -I/2), respectively. In order to develop a low-energy-spread, high brightness electron source using negative electron affinity technology, it is necessary to survey the effects of cathode structure and activation on energy spread, lateral velocity distribution, peak current, and lifetime. Most research in NEAPC technology has gone into detector applications, to improve photoyield at low light intensity and high wavelength. Intevac is a leader in this area. The scientific understanding and technical expertise developed in this effort are important to achieving our goal of an electron source optimized for low-energy electron applications; however, it will be necessary to investigate other cathode properties (peak brightness, energy spread) under a substantially different operating regime (high light intensity, small emission area, high extraction field). Significant advances were achieved in tunneling hot electron amplifiers and in the understanding of hot electron transport in the work funded by the contract and carried out by M. Heiblum and his co-workers. The results of this work are described in detail in nine papers that have been published in the open literature. (These papers are listed below as references 1-9 and copies of them are attached.) This report summarizes the principal results. There are three aspects of the work in which the results are particularly noteworthy: the demonstration of the first hot hole tunneling transistor and its use to study hot hole transport in GaAs; the successful fabrication of a hot electron 'THETA' transistor with a pseudomorphic InGaAs base which allowed high transistor gains (beta approx. = 30) to be achieved; and the conception and successful fabrication of a lateral hot electron device and its use to investigate ballistic, hot electron transport in a 2-dimensional electron gas in GaAs. The objective of this effort was the investigation of the molecular beam epitaxy trilayer Josephson junction process under development by Varian Corporation. Under this effort, Stanford University provided fundamental materials characterization to understand and improve the surfaces and interfaces of the thin film structures. HYPRES Inc. provided an independent assessment of the junctions produced by Varian and addressed the possibilities of rapid single fluxquantum (RSFQ) circuit designs. The material system chosen for this investigation was bismuth strontium calcium copper oxide (BSSCO). The Josephson junction character of the devices was confirmed by the observation of microwave induced (Shapior) steps in the I-V curves. Contact resistance was reduced by three orders of magnitude by modulation doping the top few molecular layers of the upper superconductive electrode. The desired properties to warrant RSFQ circuit fabrication were not obtained. A material system with a higher Josephson junction critical temperature and higher critical current is necessary for circuits. DTIC

The interest in monolithic integration of optoelectronic devices based on III-V semiconductors has presented a great challenge to crystal growth and device processing. Laser assisted atomic layer epitaxy (LALE) is attracting increased attention as a candidate to meet the challenge because it offers localized deposition at a control of layer thickness, doping profile, and interface roughness on an atomic scale: This work starts with a detailed study of the gas phase thermal decomposition of trimethylgallium (TMGa) and its relevance to atomic layer epitaxy (ALE) using molecular beam sampling mass spectrometry. The growth of GaAs by LALE is then first studied using triethylgallium (TMGa) and arsine (AsH3) as precursors. The influence of growth chemistry on the carbon contamination in the epilayers is further studied by using combinations of TMGa and tertiarybutylarsine (TBAs) and triethylgallium (TEGa) and AsH3. The device application of the growth technique is demonstrated for the first time through laser diodes with the GaAs QW grown by LALE. DTIC

DIGITALLY PROGRAMMABLE COMPOSITE OPERATIONAL AMPLIFIER APPLICATIONS M.S. Thesis
Ronald A. Crowell Sep. 1993 98 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275081) Avail: CASI HC A05

In this study, CMOS implementation of composite operational amplifiers onto a single chip is examined. Composite operational amplifiers are realized by interconnecting two or more single operational amplifiers in any one of four high performance circuit topologies. These high performance topologies result in composite operational amplifiers having useful bandwidths that are significantly larger than those associated with their constituent operational amplifiers without sacrificing closed loop gain. Computer simulations using PSPICE are compared with experimental results for performance evaluation. As an application, a multiple feedback bandpass filter implementation is examined. DTIC

PERFORMANCE EVALUATION OF A 22.5/30 kW 270 VOLTS DIRECT CURRENT GENERATOR SYSTEM Final Report, Jan. 1992 - 1993
John G. Nairus and David A. Criminski Dec. 1993 153 p
(AD-A275106; WL-TR-93-2025) Avail: CASI HC A08/MF A02

This report documents the electrical system performance testing of a 12-pole, wound rotor machine with integral 3:1 speed increaser and recitifer, 22.5/30 kW 270 Vdc generator system. The performance testing was accomplished in the generator test facility of the Aerospace Power Division (WL/POOC-1). This report also documents WL/POOC-I's Data Acquisition System modified for 270 Vdc test and analysis. Generator system parameters measured include transient responses to load applications and removals, ripple voltages, distortion spectrums, and fault currents. Results were compared to electrical system characteristics specified in MIL-STD-704E. DTIC

THE 100 kA, 5000 V SOLID-STATE OPENING SWITCH FOR INDUCTIVE ENERGY STORAGE Technical Report, Apr. 1990 - May 1993
Mark W. Heyse, Joshua Kolawole, Nolan E. Taconi, Jr., and Ed E. Bowles Dec. 1993 11 p
(Contract F08635-90-C-0241)
(AD-A274993; WL-TP-93-005) Avail: CASI HC A03/MF A01

Inductive energy stores have demonstrated higher energy storage densities than capacitive energy stores. A limitation in the use of inductive energy stores has been the availability of adequately rated opening switches. A self commutated solid-state switch has been developed for use as an opening device for an inductive energy store. The switch is rated at 100 kA and 5000 V and is composed of four identical 25 kA switch modules. The charging pulse lengths for the intended application vary from 0.1 to 5 seconds. Efficiency and volumetric power density were optimized. The switch topology is a two stage hybrid consisting of an SCR-FET/SCR-IGBT combination. The switch is designed to charge an inductive energy store and repetitively commutate the current into a railgun load. A 100 kA switch module has been built and successfully tested. The theory of operation, circuit topology, and test results are given in this paper. DTIC

In high-speed digital circuits, high frequency phenomena affects the characteristics of the interconnections. Physical discontinuities or nonuniformities in the connections may cause severe reflections when they can no longer be considered as conducting wires, but behave as transmission lines and/or waveguides. In multilayered digital circuits, vias constitute one of the most commonly-used class of interconnects. Vias are not good carriers of high-speed signals. They cause signal distortion and reflections as well as severe degradation in the high frequency components. The analysis and modeling of a single via and some quasi-static or quasi-TEM analyses of single via configurations have been carried out previously. To date, the analysis of coupled noise between adjacent vias has received very little attention. The major reasons include the complexity of multi-via structures and the difficulty of modeling and analyzing them accurately over a broad frequency range. DTIC

We fabricated high quality MCT diodes using in-situ grown MCT and selective annealing. We used these diodes to benchmark our initial characterization and as a basis for our irradiation modeling. We implemented the models in PISCES-IIB and compared the I-V relationship to measurements. The close match between simulations and measurements demonstrates the applicability of the models. We expanded the simulations to I-V characteristics of irradiated diodes. To do so, we developed models for the induced current mechanisms resulting from radiation interactions. The results confirm the theories concerning the radiation's effect on tunneling in MCT. The simulations also suggest that improvements require knowledge of tunneling currents associated with trap formation in MCT. DTIC

ELECTROSET TECHNOLOGY: ON THE FOREFRONT OF MANUFACTURING
Ronald P. Reitz 1993 4 p
(AD-A275166) Avail: CASI HC A01/MF A01

A newly patented technology is emerging which will help American manufacturers produce goods faster and more affordably. Additionally, manufacturers can use it to diversify their product lines by making complex parts quickly and efficiently. Its called Electroset Technology (EST). With Est, standard casting resins are modified to be electrically semiconductive while they are in their fluid state. Electroset resins are electrically polarizable particles immersed within and suspended throughout casting resins. Because they are semiconductive in their fluid state, electric energy can be applied to and through these resins during cure to do useful work. DTIC

ELECTRICAL CONDUCTIVITY MEASUREMENTS ON A SiCp/Al ALLOY METAL MATRIX COMPOSITE
E. J. Carman, A. J. Dawson, and B. Roebuck 1993 35 p
(PB94-138310; NPL-DMM(A)85) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Both DC and AC electrical conductivity measurements have been used to assess the homogeneity of several plates and thin sheets of a SiC particulate reinforced aluminum alloy metal matrix composite. The

uncertainties associated with the measurements have been assessed and are compared with the spread in values obtained from measurements on each plate. The AC measurements showed less inherent uncertainty than the DC measurements and revealed some variation from plate to plate and sheet to sheet, probably due to small differences in matrix chemistry. UNSCREENED LOW TENSION CABLES SCRAPE ABRASION TESTING. PART 1: AN INTERLABORATORY STUDY ON SCRAPE ABRASION TESTING ACCORDING TO ISO DP 6722-1
L. Spilg 1992 30 p
(ISSN 0284-5172)
(PB94-135605; ISBN-91-7848-335-2) Avail: CASI HC A03/MF A01

A proposal for revision of ISO 6722/1, Road vehicles - Unscreened low tension cables, Part I: General requirements and test methods, specifies a method for scrape abrasion testing. Tests at different laboratories indicate large variations in the results obtained using this method. It is evident that a number of parameters have influence on the results. In an effort to clarify the influence of some of these parameters, the ISO/TC 22/SC3/WG4-Low Tension Cables decided to undertake an interlaboratory test focusing on different equipment, different conductor types and different insulating materials. This report presents the method used and the result of the interlaboratory test. It is concluded that it is not possible to compare data obtained on different equipment although they are made according to standard and that further investigations have to be done before including this method in an international standard. TRANSPORT PROPERTIES OF EPITAXIAL LIFT OFF FILMS
R. A. Mena, S. E. Schacham, P. G. Young, E. J. Haugland, and S. A. Alterovitz May 1993 21 p
(RTOP 506-72-1B)
(NASA-TM-106156; E-7842; NAS 1.15:106156) Avail: CASI HC A03/MF A01

Transport properties of epitaxially lifted-off (ELO) films were characterized using conductivity, Hall, and Shubnikov-de Haas measurements. A 10-15 percent increase in the 2D electron gas concentration was observed in these films as compared with adjacent conventional samples. We believe this result to be caused by a backgating effect produced by a charge build up at the interface of the ELO film and the quartz substrate. This increase results in a substantial decrease in the quantum lifetime in the ELO samples, by 17-30 percent, but without a degradation in carrier mobility. Under persistent photoconductivity, only one subband was populated in the conventional structure, while in the ELO films the population of the second subband was clearly visible. However, the increase of the second subband concentration with increasing excitation is substantially smaller than anticipated due to screening of the backgating effect. Author (revised)

SCREENING OF FLEXIBLE CABLES BY NONLINEAR RESISTANCE MEASUREMENTS Technical Report
G. W. Stupian 10 Jan. 1994 29 p
(Contract F04701-88-C-0089)
(AD-A275193; TR-93(3404)-1; SMC-TR-93-56) Avail: CASI HC A03/MF A01

Two traces in flexible cables used in the Milstar agile beam antenna system failed during acceptance testing. The cables, essentially printed circuit boards fabricated on flexible substrates, are composed of copper-foil conductors sandwiched between insulating Kapton layers. The cables carry current pulses used in the steering circuitry for the antenna beam. Upon sectioning and inspection of the suspect cables, substantial thinning of the copper foil conductors at feedthrough connections was noted. Other cables examined also exhibited thinning of metallization. Cables with degraded metallization develop anomalously high electrical resistances or can fail 'open'. The difficulties encountered with these cables resulted from poor workmanship, and the cable manufacturer subsequently lost certification from the Defense Electronics Supply Center. However, a large number of the cables had already been installed in satellites, and the reliability of the cables is critically important to mission success. A considerable effort was, therefore, mounted by the contractors, with the support of Aerospace, to assess the extent of the problem and determine whether a suitable screening procedure could be developed so that only selective, rather than total, replacement of the cables installed on the first Milstar satellite, DFS 1, might be necessary. In the course of this investigation, a screening test based on nonlinearities in cable resistance was developed. This test was originally intended to be applied to the cables in flight hardware. In fact, the application of this test to cables still in stores uncovered additional defective cables and led to a decision to replace all flexible cables with those from another manufacturer. DTIC

FOCUSED ION BEAM FABRICATION OF MICROELECTRONIC STRUCTURES Final Report, 1 Oct. 1990 - 14 Oct. 1993
John Melngailis 30 Dec. 1993 109 p
(Contract DAAL03-90-G-0223)
(AD-A275384; ARO-28345.5-EL) Avail: CASI HC A06/MF A02

One of the most successful applications of focused ion beams has been the deposition of submicrometer conductors for integrated circuits. Our work has concentrated on demonstrating new materials and on studying the fundamental mechanisms of the deposition and milling processes. One of the important results has been the first demonstration of ion induced copper deposition from a new precursor gas. Copper is being considered a successor to aluminum in integrated circuits, and our copper had the lowest resistivity of any material produced by room temperature focused ion beam deposition. We have also studied the ion induced deposition of gold and tungsten as a function of angle of incidence as well as the milling of Si, SiO2, W, and Au. These processes are also important for the repair of lithography masks. A Monte Carlo model based on collision cascades has been developed for the fundamental mechanism for ion induced deposition and tested against measurements of deposition yield of Au for various ion energies and noble gas Ion species. The deposition appears to be substrate mediated and fits the collision cascade model. The dependent of milling and deposition as a function of ion incidence also appears to fit this model. DTIC

A composite solid electrolyte film is formed by dissolving a lithium salt such as lithium iodide in a mixture of a first solvent which is a co-solvent for the lithium salt and a binder polymer such as polyethylene oxide and a second solvent which is a solvent for the binder polymer and has poor solubility for the lithium salt. Reinforcing filler such as alumina particles are then added to form a suspension followed by the slow addition of binder polymer. The binder polymer does not agglomerate the alumina particles. The suspension is cast into a uniform film. NASA

MULTI-SPEED MULTI-PHASE RESOLVER CONVERTER Patent Application
Dean Alhorn, inventor (to NASA) and David Howard, inventor (to NASA) 22 Feb. 1994 23 p
(NASA-Case-MFS-28855-1; NAS 1.71:MFS-28855-1; US-Patent-Appl-SN-199924) Avail: CASI HC A03/MF A01

A multiphase converter circuit generates a plurality of sinusoidal outputs of displaced phase and given speed value from the output of an angular resolver system attachable to a motor excited by these multi-phase outputs, the resolver system having a lower speed value than that of the motor. The angular resolver system provides in parallel format sequential digital numbers indicative of the amount of rotation of the shaft of an angular position sensor associated with the angular resolver system. These numbers

are used to excite simultaneously identical addresses of a plurality of addressable memory systems, each memory system having stored therein at sequential addresses sequential values of a sinusoidal wavetrain of a given number of sinusoids. The stored wavetrain values represent sinusoids displaced from each other in phase according to the number of output phases desired. A digital-to-analog converter associated with each memory system converts each accessed word to a corresponding analog value to generate attendant to rotation of the angular resolver a sinusoidal wave of proper phase at each of the plurality of outputs. By properly orienting the angular resolver system with respect to the rotor of the motor, essentially ripple-free torque is supplied to the rotor. The angular resolver system may employ an analog resolver feeding an integrated circuit resolver-to-digital converter to produce the requisite digital values serving as addresses. Alternative versions employing incremental or absolute encoders are also described. NASA

METHOD OF IMPLEMENTING DIGITAL PHASE-LOCKED LOOPS Patent Application

Scott A. Stephens, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and Jess Brooks Thomas, Jr., inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 13 Oct. 1993 89 p

(Contract NAS7-918)

(NASA-Case-NPO-18757-1-CU; NAS 1.71:NPO-18757-1-CU; US-Patent-Appl-SN-141797) Avail: CASI HC A05/MF A01

In a new formulation for digital phase-locked loops, loop-filter constants are determined from loop roots that can each be selectively placed in the s-plane on the basis of a new set of parameters, each with simple and direct physical meaning in terms of loop noise bandwidth, root-specific decay rate, or root-specific damping. Loops of first to fourth order are treated in the continuous-update approximation (BLT yields 0) and in a discrete-update formulation with arbitrary BLT. Deficiencies of the continuous-update approximation in large-BLT applications are avoided in the new discrete-update formulation. A new method for direct, transient-free acquisition with third- and fourth-order loops can improve the versatility and reliability of acquisition with such loops. NASA

DENDRITE PREVENTING SEPARATOR FOR SECONDARY LITHIUM BATTERIES Patent Application

David H. Shen, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Subbarao Surampudi, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), Chen-Kuo Huang, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.), and Gerald Halpert, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 17 Nov. 1993 13 p

(Contract NAS7-918)

(NASA-Case-NPO-18585-1-CU; NAS 1.71:NPO-18585-1-CU; US-Patent-Appl-SN-154322) Avail: CASI HC A03/MF A01

Dendrites are prevented from shorting a secondary lithium battery by use of a first porous separator, such as porous polypropylene, adjacent to the lithium anode that is unreactive with lithium and a second porous fluoropolymer separator between the cathode and the first separator, such as polytetrafluoroethylene, that is reactive with lithium. As the tip of a lithium dendrite contacts the second separator, an exothermic reaction occurs locally between the lithium dendrite and the fluoropolymer separator. This results in the prevention of the dendrite propagation to the cathode. NASA

NONVOLATILE PROGRAMMABLE NEURAL NETWORK SYNAPTIC ARRAY Patent

Raoul Tawel, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 29 Mar. 1994 10 p Filed 8 Jul. 1992 Supersedes N92-30086 (30 - 20, p 3442)

(NASA-Case-NPO-18578-1-CU; US-Patent-5,298,796; US-Patent-Appl-SN-912956; US-Patent-Class-307-201; US-Patent-Class-395-24; US-Patent-Class-395-25; US-Patent-Class-257-323; Int-Patent-Class-H03K-19/08) Avail: US Patent and Trademark Office

A floating-gate metal oxide semiconductor (MOS) transistor is implemented for use as a nonvolatile analog storage element of a synaptic cell used to implement an array of processing synaptic cells. These cells are based on a four-quadrant analog multiplier requiring both X and Y differential inputs, where one Y input is UV programmable. These nonvolatile synaptic cells are disclosed fully connected in a 32 x 32 synaptic cell array using standard very large scale integration (VLSI) complementary MOS (CMOS) technology.

THE INFLUENCE OF TEMPERATURE ON MICROELECTRONIC DEVICE FAILURE MECHANISMS, PHASE 2 Final Report

Michael Pecht 4 Sep. 1993 283 p

(Contract DAAL01-91-C-0142)

(AD-A275029) Avail: CASI HC A13/MF A03

There has been a common belief that reliable electronics can be achieved by lowering temperature. Elevated temperature has in the past been

considered a dominant stress that lowers reliability, so every effort has been made to lower operating temperature until the desired reliability is achieved. The belief in the harmful effects of temperature has woven itself into today's screening and thermal derating processes. High-reliability applications require that the microelectronic device be subjected to high-temperature stress screens, like burn-in, to improve the reliability of the product. Moreover, thermal derating measures for microelectronics often involve lowering temperature. DTIC

QUANTUM INTERFERENCE PHENOMENA AND NOVEL SWITCHING IN SPLIT GATE HIGH ELECTRON MOBILITY TRANSISTORS Ph.D. Thesis
Jong-Ching Wu 1992 120 p
Avail: Univ. Microfilms Order No. DA9313325

Nanometer scale electronic channels with and without a discontinuity were made in modulation-doped AlGaAs/GaAs heterojunctions using a split gate technique. Quantum interference phenomena in an electron cavity and fast switching behavior due to hot electron effects in a lateral double potential barrier structure were explored. First, one dimensional channels with a double bend discontinuity were examined in the mK temperature range. Low-field ac-conductance measurements have evidenced quantum waveguide effects: resonant features were observed in the one dimensional conductance plateaus in which the number of peaks was directly related to the geometry of the double bend. Temperature and magnetic field studies, along with a standing wave model, have provided a better understanding of quantum interference phenomena in electron wave guide and cavity structures. Secondly, a structure containing two cascaded double bend discontinuities was studied. The structure behaves as a constricted cavity coupling two point-contacts, in which the depletion by the split gate was used to form and control the lateral double potential barriers. The low temperature source-drain characteristics exhibited a pronounced S-shaped negative differential conductance that can be attributed to a nonlinear electron temperature effect along the conducting path. The data presented show two types of conducting state: electron tunneling in the off state and hot electron conduction (thermionic emission) in the on state. The estimated switching speed of the device could be as fast as 5 ps due to short transit time. Dissert. Abstr.

YIELD AND VARIABILITY OPTIMIZATION OF INTEGRATED CIRCUITS: PRINCIPLES AND PRACTICAL SOLUTIONS Ph.D. Thesis
Jian Cheng Zhang 1992 194 p
Avail: Univ. Microfilms Order No. DA9315171

This dissertation deals with both theoretical and practical aspects of integrated circuits (IC's) statistical design. It stresses and explains that the essential difference between IC statistical design and discrete circuit statistical design lies in basic statistical features of two types of circuits. The main emphasis of the research is placed on principles and practical solutions for performance variability minimization rather than manufacturing yield enhancement alone. A variability gradient formula applicable to a general IC statistical model is first developed, which leads to understanding of the nature of IC variability minimization problem, forms a theoretical basis for the possibility of IC variability minimization, and clarifies the principles of variability minimization and performance tuning. A two-stage strategy, based on separate performance variability minimization and separate performance tuning, is proposed. Practical results show that the two-stage procedure leads to small variability, small 'bias,' and high yield. The use of orthogonal array based design of experiments is advocated for exploring the effects of circuit variables on circuit performances, which aims at eliminating noncritical circuit parameters in order to reduce problem dimension. Several design plans are considered for a variety of applications. The level 3 main effect orthogonal array design approach is used for statistical gradient estimation and applied together with the stochastic approximation method to yield optimization. Taguchi experiments are used to explore the interactions of designable circuit parameters and noise factors, leading to efficient estimation of gradient of variability, and gradient of the mean, in order to identify the parameters essential for variability minimization and performance tuning. The mathematical model corresponding to Taguchi experiments is also studied. The worst-case measure is considered as another measure of performance variability. It is of great importance for digital delay circuits. Mathematical interpretations are provided to bridge the gap between variability minimization and worst-case measure reduction, and make the underlying principles and methods for variability minimization equally applicable to the worst-case measure reduction. The research also goes one step further by using fuzzy set theory as a framework to handle statistical optimization with multiple circuit performances. Dissert. Abstr.

(Contract DE-AC04-94AL-85000)
(DE94-005288; SAND-93-3984C; CONF-940206-1) Avail: CASI HC A02/MF A01

This paper focuses on the development of an approximate time-optimal feedback strategy for conducting rest-to-rest maneuvers of a magnetically levitated table. Classical switching curves are modified to account for the complexities of magnetic actuation as well as the coupling of the rigid body modes through the control. A smooth blend of time-optimal and

proportional-derivative controls is realized near the destination point to correct for inaccuracies produced by the approximate time-optimal strategy. Detailed computer simulations of the system indicate that this hybrid control strategy provides a significant reduction in settling time as compared to proportional-derivative control alone. DOE

INTERBAND OPTICAL ABSORPTION IN THE WANNIER-STARK LADDER UNDER THE ELECTRON-LO-PHONON RESONANCE CONDITION
A. O. Govorov Aug. 1993 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-608097; IC-93/258) Avail: CASI HC A03 (US Sales Only)

Interband optical absorption in the Wannier-Stark ladder in the presence of the electron-LO-phonon resonance is investigated theoretically. The electron-LO-phonon resonance occurs when the energy spacing between adjacent Stark-ladder levels coincides with the LO-phonon energy. We propose a model describing the polaron effect in a superlattice. Calculations show that the absorption line shape is strongly modified due to the polaron effect under the electron-LO-phonon resonance condition. We consider optical phenomena in a normal magnetic field that leads to enhancement of polaron effects. DOE

Rainee N. Simons (Sverdrup Technology, Inc., Brook Park, OH.), Eron S. Kelly (Princeton Univ., NJ.), Richard Q. Lee, and Susan R. Taub Apr. 1994 6 p Proposed for presentation at the 1994 IEEE AP-S International Symposium and URSI Radio Science Meeting, Seattle, WA, 19-24 Jun. 1994; sponsored by IEEE
(Contract NAS3-25266; RTOP 506-44-2C)
(NASA-TM-106540; E-8683; NAS 1.15:106540) Avail: CASI HC A02/MF A01

In mobile and satellite communications there is a need for low cost and low profile antennas which have a toroidal pattern. Antennas that have been developed for mobile communications include a L-Band electronically steered stripline phased array, a Ka-Band mechanically steered elliptical reflector antenna and a Ka-Band printed dipole. In addition, a L-Band mechanically steered microstrip array, a L-Band microstrip phased array tracking antenna for mounting on a car roof and an X-Band radial line slotted waveguide antenna have been demonstrated. In the above electronically scanned printed arrays, the individual element radiates normally to the plane of the array and hence require a phase shifter to scan the beam towards the horizon. Scanning in the azimuth is by mechanical or electronic steering. An alternate approach is to mount microstrip patch radiators on the surface of a cone to achieve the required elevation angle. The array then scans in the azimuth by beam switching. Author

A BIPOLAR ANALOG FRONT-END INTEGRATED CIRCUIT FOR THE SDC SILICON TRACKER
I. Kipnis, H. Spieler, and T. Collins Nov. 1993 9 p Presented at the 1993 IEEE Nuclear Science Symposium and Medical Imaging Conference, San Francisco, CA, 2-5 Nov. 1993
(Contract DE-AC03-76SF-00098)
(DE94-005203; LBL-34864; CONF-931107-32) Avail: CASI HC A02/MF A01

A low noise, low power, high bandwidth, radiation hard, silicon bipolar transistor full-custom integrated circuit (IC) containing 64 channels of analog signal processing has been developed for the SDC silicon tracker. The IC was designed and tested at LBL and was fabricated using CBIC-U2, 4 GHz f(sub T) complementary bipolar technology. Each channel contains the following functions: low noise preamplification, pulse shaping, and threshold discrimination. This is the first iteration of the production analog IC for the SDC silicon tracker. The IC is laid out to directly match the 50 micron pitch double-sided silicon strip detector. The chip measures 6.8 mm by 3.1 mm and contains 3,600 transistors. Three stages of amplification provide 180 mV/fC of gain with a 35 nsec peaking time at the comparator input. For a 14 pF detector capacitance, the equivalent noise charge is 1300 el. rms at a power consumption of 1 mW/channel from a single 3.5 V supply. With the discriminator threshold set to four times the noise level, a 16 nsec time-walk for 1.25 to 10 fC signals is achieved using a time-walk compensation network. Irradiation tests at TRIUMF to a Phi = 10(exp 14) protons/sq cm have been performed on the IC, demonstrating the radiation hardness of the complementary bipolar process. DOE

A TRANSMISSION-LOSS MONITOR USING CURRENT TRANSFORMERS
J. F. Power, J. D. Gilpatrick, and A. J. Jason 1993 7 p Presented at the Beam Instrumentation Workshop, Santa Fe, NM, 20-23 Oct. 1993
(Contract W-7405-eng-36)
(DE94-003974; LA-UR-93-3704; CONF-9310204-13) Avail: CASI HC A02/MF A01

A system for measuring the amount of beam-charge loss in a linear-accelerator structure has been developed that uses a pair of beam-current transformers, otherwise used to monitor the linac beam current. This system is necessary to enable the Ground Test Accelerator (GTA) fast-protect system to shut off the accelerated beam in the event of a beam loss that would deposit sufficient energy to damage the accelerator structure. The present GTA accelerator consists of a 2.5-MeV, H(-) RFQ, an intermediate matching section (IMS) and a single DTL cavity with an output energy of 3.2-MeV and transmitted current of 35 mA. Based on the RFQ output beam, melting of the copper structures will occur when about 40 nC of beam is deposited in a point loss. For a grazing angle of 30 mrad, up to 640 nC may be tolerated. The beam-current-transmission-loss monitor (BCTLM) system in conjunction with the fast-protect system measures the amount of beam loss between two toroidal beam-current monitors and automatically terminates the macropulse when the integrated loss reaches a predetermined set point. The design and operation of the BCTLM system used in the IMS and DTL section of the accelerator is described. DOE

GUIDANCE ON ELIMINATING INTERFERENCE FROM SENSITIVE ELECTRICAL CIRCUITS
B. P. Kibble and I. A. Robinson Oct. 1993 38 p
(ISSN 0143-7305)
(PB94-139300; NPL-DES-129; ETN-94-95847) Copyright Avail: Issuing Activity (National Physical Lab., Teddington, Middlesex TW11 0LW, England)

The basic principles underlying the elimination of electrical interference from circuits, which is necessary in order that their sensitivities can approach the fundamental Johnson noise limit, are presented. Eliminating all possible sources of extraneous interference is vital for the successful performance of sensitive analog electrical measurements. If interference is present, not only is the resolution of the measurement impaired through degradation of the signal to noise ratio, but rectification of the interference by any of the myriad semiconductor rectifying junctions in electronic signal detectors may well result in systematic error. Focus is on electrical interference, whose elimination depends on applying a very few elementary principles or circuit coupling. ESA

DESIGN OF A VARIABLE-CONDUCTANCE VACUUM INSULATION
D. K. Benson, T. F. Potter, and C. E. Tracy Jan. 1994 8 p Presented at the Society of Automotive Engineers (SAE) Congress and Exposition, Detroit, MI, 28 Feb. - 3 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC02-83CH-10093)
(DE94-000270; NREL/TP-452-5814; CONF-940242-3) Avail: CASI HC A02

This paper describes one approach to the design of variable-conductance vacuum insulation. In this design, the vacuum insulation consists of a permanently sealed, thin sheet steel, evacuated envelope of whatever geometry is required for the application. The steel envelope is supported internally against the atmospheric pressure loads by an array of discrete, low-conductance, ceramic supports, and radiative heat transfer is blocked by layers of thin metal radiation shields. Thermal conductance through this insulation is controlled electronically by changing the temperature of a small metal hydride connected to the vacuum envelope. The hydride reversibly absorbs/desorbs hydrogen to produce a hydrogen pressure typically within the range from less than 10(exp -6) to as much as 1 torr. Design calculations are compared with results from laboratory tests of bench scale samples, and some possible automotive applications for this variable-conductance vacuum insulation are suggested. (Contract DE-AC02-76CH-03000)
(DE94-006040; FNAL-TM-1870) Avail: Issuing Activity (Department of Energy (DOE))

This note describes a low voltage signal detector that is useful for detecting quenches or excessive lead voltages at superconducting magnets. It can also be used for other applications where it is needed to detect low level signals present on high voltage installations. The application of isolated operational amplifiers is often not practical for high voltage applications because of their limited input voltage rating, common mode rejection, and sensitivity. The described detector can withstand 7.5 kV input to ground voltage. It has a typical common mode rejection of -150 dB at 60 Hz and an input sensitivity better than 1 mV. The magnetically coupled quench detector assembly is very sensitive to extremely small (order of 1 micro-Amp) current changes in the sense windings. The detector assembly can therefore also be referred to as a micro current detector. DOE

AC LOSSES FOR THE SELF FIELD OF AN AC TRANSPORT CURRENT WITH A DC TRANSPORT CURRENT OFFSET IN HIGH T(c) SUPERCONDUCTING MAGNET COILS FOR MagLev APPLICATION
V. F. Koosh Oct. 1993 17 p
(Contract DE-AC02-76CH-00016)
(DE94-005187; BNL-49706) Avail: CASI HC A03/MF A01

Although much research has been conducted concerning the losses of high-T(sub c) superconductors, very little has concentrated on the self-field losses in an actual magnet arrangement. The coils studied in this work were designed for use as actual magnets in an industrial application. Self field loss measurements were made upon tape-wound 2223 superconducting helix coils. The self-field losses were produced by an AC transport current with a DC transport current offset. Losses were taken for single, double and triple tape windings, giving essentially monofilament, dual, and three filament cases. The losses measured here were varied over a range of AC current values for several different DC values, and over a range of frequencies. The currents were all AC sinusoids with a DC offset. All measurements were made at T = 77K. DOE

THE AUTOMATED ROTATING SHADOWBAND SPECTRORADIOMETER
L. Harrison, M. A. Beik, and J. J. Michalsky 1993 4 p Presented at the Optical Society of America Meeting on Optical Remote Sensing of the Atmosphere, Salt Lake City, UT, 8-12 Mar. 1993
(Contracts DE-FG02-90ER-61072; DE-AC06-76RL-01830)
(DE94-001878; DOE/ER-61072/7; CONF-930346-5) Avail: CASI HC A01/MF A01

We are developing a photodiode array rotating shadowband spectroradiometer (RSS) as part of the Instrument Development Program (IDP) of the Atmospheric Radiation Measurement (ARM) program of the U.S. Department of Energy (DOE). This instrument uses the automated rotating shadowband technique to separate and measure the spectrally resolved direct-normal, total horizontal, and diffuse horizontal irradiances in the 360 to 1060 nm wavelength region. It is intended as an instrument for the central facility of each of the cloud and radiation testbed (CART) sites, and it will complement the array of multi-filter rotating shadowband radiometers (MFRSR) currently being deployed by ARM and other research programs including TOGA/COARE. MODELING TURBULENCE IN FLOWS WITH A STRONG ROTATIONAL COMPONENT
D. E. Burgess and P. J. ORourke Nov. 1993 27 p
(Contract W-7405-eng-36)
(DE94-003577; LA-12552-MS) Avail: CASI HC A03/MF A01

We consider the effectiveness of various turbulence models in flows with a strong rotational component. To evaluate the models, we implement them into a one-dimensional test code and make comparisons with experimental data for swirling flow in a cylinder. The k-epsilon type turbulence models do poorly in predicting the experimental results. However, we find that the incorporation of a Reynolds stress evolution equation gives good agreement with the experimentally measured mean flow. Modeling the pressure-strain correlation tensor correctly is the key for obtaining good results. A combination of Launder's basic model together with Yakhot's dissipation rate equation works best in predicting both the mean flow and the turbulence intensity. DOE

ANALYSIS OF SPARK-INDUCED BUBBLE EXPERIMENTS USING CALE
S. C. Simonson, III and S. W. McAllister Oct. 1993 69 p
(Contract W-7405-eng-48)
(DE94-003667; UCRL-ID-115283) Avail: CASI HC A04/MF A01

Calculations were made using the 2-D hydrodynamics code CALE of underwater bubble oscillations and collapse for two situations of interest in the development of underwater acoustic sources. The first is the case of a single bubble to which energy is added to prolong oscillations. The second is the case of a three-bubble array, which typifies one end element in a linear array. Comparisons were made with a series of experiments with spark-induced bubbles carried out at Tetra Corp. The bubbles were made at a depth of 64 cm with periods of about 400 micro-s. One dimensional calculations were used to study singlebubbles. The 1-D results showed that energy needs to be added at a precise phase in order to promote bubble re-excitation. The experiments showed evidence of losses caused by interaction with the relatively large electrodes upon collapse, leading to a 50 percent reduction in amplitude and period of the second oscillation. When a second discharge was made at the end of the first oscillation, the next oscillation had 80 percent of the amplitude of the first. This can be interpreted either as formation of a new bubble, or as pumping the previous bubble, both occurring in a disturbed environment. Two-dimensional calculations were used to study the three-bubble array. The 2-D results showed significant interaction between the central and side bubbles, leading to jetting. For the particular combination of size and spacing used, jetting occurred in the third oscillation of the bubbles. DOE

SAFSIM THEORY MANUAL: A COMPUTER PROGRAM FOR THE ENGINEERING SIMULATION OF FLOW SYSTEMS
Dean Dobranich Dec. 1993 200 p
(Contract DE-AC04-94AL-85000)
(DE94-005381; SAND-92-0693) Avail: CASI HC A09/MF A03

SAFSIM (System Analysis Flow SIMulator) is a FORTRAN computer program for simulating the integrated performance of complex flow systems. SAFSIM provides sufficient versatility to allow the engineering simulation of almost any system, from a backyard sprinkler system to a clustered nuclear reactor propulsion system. In addition to versatility, speed and robustness are primary SAFSIM development goals. SAFSIM contains three basic physics modules: (1) a fluid mechanics module with flow network capability; (2) a structure heat transfer module with multiple convection and radiation exchange surface capability; and (3) a point reactor dynamics module with reactivity feedback and decay heat capability. Any or all of the physics modules can be implemented, as the problem dictates. SAFSIM can be used for compressible and incompressible, single-phase, multicomponent flow systems. Both the fluid mechanics and structure heat transfer modules employ a one-dimensional finite element modeling approach. This document contains a description of the theory incorporated in SAFSIM, including the governing equations, the numerical methods, and the overall system solution strategies. DOE

LARGE EDDY SIMULATIONS USING LATTICE BOLTZMANN ALGORITHMS
J. D. Serling 28 Sep. 1993 21 p
(Contract W-7405-eng-36)
(DE94-005666; LA-SUB-94-1) Avail: CASI HC A03/MF A01

This report contains the results of a study performed to implement eddy-viscosity models for Large-Eddy-Simulations (LES) into Lattice Boltzmann (LB) algorithms for simulating fluid flows. This implementation requires modification of the LB method of simulating the incompressible Navier-Stokes equations to allow simulation of the filtered Navier-Stokes equations with some subgrid model for the Reynolds stress term. We demonstrate that the LB method can indeed be used for LES by simply locally adjusting the value of the BGK relaxation time to obtain the desired eddy-viscosity. Thus, many forms of eddy-viscosity models including the standard Smagorinsky model or the Dynamic model may be implemented using LB algorithms. Since underresolved LB simulations often lead to instability, the LES model actually serves to stabilize the method. An alternative method of ensuring stability is presented which requires that entropy increase during the collision step of the LB method. Thus, an alternative collision operator is locally applied if the entropy becomes too low. This stable LB method then acts as an LES scheme that effectively introduces its own eddy viscosity to damp short wavelength oscillations. DOE

BOUNDARY LAYERS INDUCED BY THREE-DIMENSIONAL VORTEX LOOPS Final Report, 1 May 1989 - 31 Aug. 1993
A. T. Conlisk, H. Affes, O. R. Burggraf, and Zhenhua Xiao Dec. 1993 278 p
(Contract DAAL03-89-K-0095)
(AD-A275678; RF-767440/722045; ARO-26595.7-EG) Avail: CASI HC A13/MF A03

The flow field generated by a helicopter in flight is extremely complex and it has been recognized that interactions between different components can significantly affect helicopter performance. In particular, the effects of the interaction between the rotor wake and the helicopter fuselage are extremely difficult to predict and pose a challenging problem for researchers and designers in the rotorcraft area. In the present work, a model for the interaction of a rotor-tip-vortex with the airframe of a helicopter is developed. The present report describes the calculation of the motion of the tip-vortex toward the airframe, the calculation of the induced pressure on the airframe, and the calculation of the boundary-layer flow under the vortex during the time period prior to the time when a portion of the tip-vortex collides with the airframe. DEVELOPMENT OF LASER VELOCIMETRY FOR THE MEASUREMENTS OF TURBULENCE INTENSITY AND FLOW VELOCITY AHEAD OF A NGV ROW IN A FULL-STAGE ROTATING TURBINE Final Report, 1985 - 1993
Sep. 1993 12 p
(Contract F33615-85-C-2566)
(AD-A275712; WL-TR-94-2008) Avail: CASI HC A03/MF A01

This is a letter report which summarizes the six tasks of this effort. It was not possible to complete shock tube measurements as originally planned due to schedule conflicts, equipment failures, and finally an explosion in Calspan's lab. The funding was to expire in 1993, which would have incurred an additional obligation of the government if the effort were to be completed as originally planned. By mutual agreement, in order to prevent incurring any additional cost, the design, fabrication, calibration and installation of heat flux gages on the Advanced High Work turbine hardware was substituted for the only uncompleted task of the effort, that of actually running the shock tube test. The documentation of the delivered hardware's performance will be reported in the appropriate ATARR test report of the Advanced High Work Turbine. The resulting new instrumentation from this modification to the Statement of Work is shown as installed on the Advanced High Work Turbine in photos. DTIC

A METHOD FOR THE MODELLING OF POROUS AND SOLID WIND TUNNEL WALLS IN COMPUTATIONAL FLUID DYNAMICS CODES
Thomas John Beutner Dec. 1993 124 p

(Contract NCC2-55)
(NASA-CR-195699; NAS 1.26:195699; JIAA-TR-111) Avail: CASI HC A06/MF A02

Porous wall wind tunnels have been used for several decades and have proven effective in reducing wall interference effects in both low speed and transonic testing. They allow for testing through Mach 1, reduce blockage effects and reduce shock wave reflections in the test section. Their usefulness in developing computational fluid dynamics (CFD) codes has been limited, however, by the difficulties associated with modelling the effect of a porous wall in CFD codes. Previous approaches to modelling porous wall effects have depended either upon a simplified linear boundary condition, which has proven inadequate, or upon detailed measurements of the normal velocity near the wall, which require extensive wind tunnel time. The current work was initiated in an effort to find a simple, accurate method of modelling a porous wall boundary condition in CFD codes. The development of such a method would allow data from porous wall wind tunnels to be used more readily in validating CFD codes. This would be beneficial when transonic validations are desired, or when large models are used to achieve high Reynolds numbers in testing. A computational and experimental study was undertaken to investigate a new method of modelling solid and porous wall boundary conditions in CFD codes. The method utilized experimental measurements at the walls to develop a flow field solution based on the method of singularities. This flow field solution was then imposed as a pressure boundary condition in a CFD simulation of the internal flow field. The effectiveness of this method in describing the effect of porosity changes on the wall was investigated. Also, the effectiveness of this method when only sparse experimental measurements were available has been investigated. The current work demonstrated this approach for low speed flows and compared the results with experimental data obtained from a heavily instrumented variable porosity test section. The approach developed was simple, computationally inexpensive, and did not require extensive or intrusive measurements of the boundary conditions during the wind tunnel test. It may be applied to both solid and porous wall wind tunnel tests. Author

SPIN-UP IN A RECTANGULAR CYLINDER M.S. Thesis
Dawn L. Stewart Dec. 1993 70 p
(AD-A275465; AFIT/CI/CIA-93-163) Avail: CASI HC A04/MF A01

We examined the spin-up from rest of water in a rectangular cylinder. The presence of corners in the cylinder causes the formation of eddies. We found that the number of eddies, as well as eddy size, position, and rotation rate were dependent on the aspect ratio of the cylinder, the depth of the fluid, and the final angular velocity of the cylinder. Two time scales were found to be important in this experiment: the traditional Ekman number based on depth, which defines the time scale required for spin-up and an additional Ekman number based on the cylinder length which provides some information about the evolution of the fluid pathlines in route to spin-up. This second Eckman number appears to provide an explanation for both the agreement and disagreement of the experimental results herein and previously published results. DTIC

WALL PRESSURE EVENTS FROM THE DIRECT NUMERICAL SIMULATION OF A TURBULENT WALL-BOUNDED FLOW Final Report
Richard M. Lueptow 6 Dec. 1993 17 p
(AD-A275890; NUWC-NPt-TR-10481) Avail: CASI HC A03/MF A01

Wall pressure events beneath a turbulent wall-bounded flow are related to turbulence-generating events in the flow. The data base for a direct numerical simulation of channel flow allows the analysis of significant pressure events in space and time. Both positive and negative wall pressure events in the data base were detected with a pressure peak conditional sampling technique. The recovered events were ensemble averaged to provide a space and time record of a typical event. Both positive and negative pressure peak events have regions of pressure of the opposite sign just ahead of and just behind them, but the regions of opposite sign do not extend to the sides of the events. Although a positive pressure peak event begins as a double positive pressure hump, the downstream hump eventually dominates and becomes the pressure peak before the event decays. Negative pressure peak events begin as a positive hump leading a negative hump. The negative hump grows to become the peak before decaying. Both positive and negative events begin about 400 wall units upstream of where the maximum pressure occurs and persist to about 400 wall units downstream of the pressure peak. The entire event lasts about 0.4 delta/U Tau. DTIC

A FLOW VISUALIZATION STUDY OF ACOUSTICALLY ENHANCED HAIRPIN VORTICES M.S. Thesis
Stephen A. Whyte 1993 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275467; AFIT/CI/CIA-93-164) Avail: CASI HC A04

For many years the turbulent boundary layer was thought to be composed of totally chaotic and random eddies. However, recent work has shown that a very organized array of structures exists in this regime. These structures, named hairpin, horseshoe, or Lamda-shaped vortices, compose a major portion of the turbulent boundary layer and may be responsible for the increased heat transfer seen in turbulent regimes. The hairpin vortex is a vortex line that has been lifted off of the surface and through mutual induction of its legs forms a loop. This loop is composed of two counter-rotating legs, oriented at 45 degrees to the wall, with a head that joins the two legs together. These legs act like tornados sweeping along the wall. They transport air adjacent to the wall up through the legs and into the head. Research at the University of Washington has shown that this 'tornado effect' increased the heat flux away from the wall. If this capability can be harnessed and enhanced, the effects of film cooling in turbine engines can be dramatically increased. DTIC

CALCULATION OF PROPULSIVE NOZZLE FLOWFIELDS IN MULTIDIFFUSING CHEMICALLY REACTING ENVIRONMENTS Ph.D. Thesis - Purdue Univ.
Kenneth John Kacynski Apr. 1994 295 p
(RTOP 506-42-72)
(NASA-TM-106532; E-8665; NAS 1.15:106532) Avail: CASI HC A13/MF A03

An advanced engineering model has been developed to aid in the analysis and design of hydrogen/oxygen chemical rocket engines. The complete multispecies, chemically reacting and multidiffusing Navier-Stokes equations are modelled, including the Soret thermal diffusion and the Dufour energy transfer terms. In addition to the spectrum of multispecies aspects developed, the model developed in this study is also conservative in axisymmetric flow for both inviscid and viscous flow environments and the boundary conditions employ a viscous, chemically reacting, reference plane characteristics method. Demonstration cases are presented for a 1030:1 area ratio nozzle, a 25 lbf film cooled nozzle, and a transpiration cooled plug and spool rocket engine. The results indicate that the thrust coefficient predictions of the 1030:1 and the 25 lbf film cooled nozzle are within 0.2 to 0.5 percent, respectively, of experimental measurements when all of the chemical reaction and diffusion terms are considered. Further, the model's predictions agree very well with the heat transfer measurements made in all of the nozzle test cases. The Soret thermal diffusion term is demonstrated to have a significant effect on the predicted mass fraction of hydrogen along the wall of the nozzle in both the laminar flow 1030:1 nozzle and the turbulent flow plug and spool nozzle analysis cases performed. Further, the Soret term was shown to represent an important fraction of the diffusion fluxes occurring in a transpiration cooled rocket engine. Author

[THE MOTION OF DEFORMING BODIES] Progress Report
Athanasios E. Tzavaras 1993 3 p
(Contract N00014-93-1-0015)
(AD-A275224) Avail: CASI HC A01/MF A01

This effort concentrated in the study of self-similar viscous and fluid-dynamic limits. The invariance of hyperbolic systems of conservation laws under dilations of coordinates is a key property underlying much of the current theory. Viscous perturbations introduce an additional parabolic scale and this invariance is lost. Understanding how the two scales interact for small viscosities is an important step in the process of studying viscous limits for general solutions. One illuminating step in that direction is to consider the Riemann problem and to study artificial regularizations, rigged so as to preserve the invariance under dilations of coordinates and the entropy structure of the system. It provides information on how viscosity

regularizes the whole wave fan emerging from Riemann data. At the technical level, it leads to study of singular perturbations for non-autonomous boundary-value problems, and the limiting process involves variation estimates. DTIC

THEORETICAL STUDY OF THE INCOMPRESSIBLE NAVIER-STOKES EQUATIONS BY THE LEAST-SQUARES METHOD
Bo-Nan Jiang, Ching Y. Loh, and Louis A. Povinelli Mar. 1994 46 p
(Contract NCC3-233; RTOP 505-90-5K)
(NASA-TM-106535; ICOMP-94-04; E-8670; NAS 1.15:106535) Avail: CASI HC A03/MF A01

Usually the theoretical analysis of the Navier-Stokes equations is conducted via the Galerkin method which leads to difficult saddle-point problems. This paper demonstrates that the least-squares method is a useful alternative tool for the theoretical study of partial differential equations since it leads to minimization problems which can often be treated by an elementary technique. The principal part of the Navier-Stokes equations in the first-order velocity-pressure-vorticity formulation consists of two div-curl systems, so the three-dimensional div-curl system is thoroughly studied at first. By introducing a dummy variable and by using the least-squares method, this paper shows that the div-curl system is properly determined and elliptic, and has a unique solution. The same technique then is employed to prove that the Stokes equations are properly determined and elliptic, and that four boundary conditions on a fixed boundary are required for three-dimensional problems. This paper also shows that under four combinations of non-standard boundary conditions the solution of the Stokes equations is unique. This paper emphasizes the application of the least-squares method and the div-curl method to derive a high-order version of differential equations and additional boundary conditions. In this paper, an elementary method (integration by parts) is used to prove Friedrichs' inequalities related to the div and curl operators which play an essential role in the analysis. ADVANCED DIAGNOSTICS FOR REACTING FLOWS Annual Technical Report, 1 Nov. 1992 - 31 Oct. 1993
R. K. Hanson 24 Nov. 1993 123 p
(Grant AF-AFOSR-0067-89)
(AD-A275057; AFOSR-94-0030TR) Avail: CASI HC A06/MF A02

Progress is reported for the past year of an interdisciplinary program aimed at establishing advanced optical diagnostic techniques applicable to combustion gases and plasmas, with some emphasis on high speed flows. The primary parameters of interest are species concentrations (including electrons), temperature, mass density, pressure, velocity, and quantities derivable from these parameters such as mass flow rate (from the product of density and velocity). The techniques under study are based on laser spectroscopy, particularly laser absorption and laser-induced fluorescence, with the latter capable of providing both single-point and multi-point (2-D and 3-D) measurements. Laser sources include tunable cw lasers (ring dye and semiconductor diode lasers) and tunable pulsed lasers (excimer-pumped dye and narrow-linewidth excimer). The cw lasers are spectrally narrow, allowing study of a new class of techniques based on spectral lineshapes and shifts, while the pulsed lasers provide intense bursts of photons needed for techniques based on light-scattering phenomena. INTERACTION OF MULTIPLE SPARK-GENERATED BUBBLES IN A COMPRESSIBLE LIQUID
Jeffrey A. Cook 1 Jun. 1993 160 p
(Contracts N00014-91-J-1366; N00014-93-J-0018)
(AD-A275037; ARL-TR-93-10) Avail: CASI HC A08/MF A02

This dissertation describes the interaction of bubbles generated by underwater electrical discharges. The oscillations of these high temperature vapor and plasma bubbles generate acoustic signatures similar to the signatures generated by air guns, underwater explosions, and combustible sources. Tasks performed by these hydrodynamic sources typically require multiple sources in an array to achieve a directional beam. The properties of a single isolated source can be used to estimate the properties of an array of multiple sources, but in many cases, the acoustic properties of the source change dramatically when several sources are placed near one another. A set of model equations was developed in this report that allowed the time evolution of the bubble generated by a spark discharge to be calculated numerically from a given discharge. A simple interaction scheme was used to couple the model equations for multiple bubbles. The coupled equations were integrated simultaneously to determine the dynamics of the elements. An apparatus containing seven individual spark discharge elements was designed and constructed to test the interaction model experimentally. The model and experimental data agreed over separations down to a few bubble diameters, and the study described when the interaction between bubbles could be neglected. DTIC

BOUNDARY LAYER COHERENT STRUCTURES Report, 1993
Hampton N. Shirer and George S. Young 1993 5 p
(AD-A275007) Avail: CASI HC A01/MF A01

The correlation dimension D is used commonly to quantify the chaotic structure of an attractor of a smooth dynamical system. The standard algorithm for estimating the value of D is based on finding the mean slope of the curve obtained by plotting ln C(r) versus ln r, where C(r) is the correlation integral and r is the distance between points on the attractor. The alternative, probabilistic method proposed by Takens is based on finding the sample means of the random variable ln(r/p), expressed as the conditional expected value E(ln(r/p):r<p). In this article, this first Takens estimator is extended and generalized. DTIC

THEORETICAL INVESTIGATION OF GAS-SURFACE INTERACTIONS Final Technical Report, 1 Sep. 1988 - 31 Jan. 1994
Kenneth G. Dyall 14 Apr. 1994 9 p
(Contract NCC2-552)
(NASA-CR-195755; NAS 1.26:195755) Avail: CASI HC A02/MF A01

The goal of this project was to develop computational tools for the calculation of the electronic structure of molecules containing heavy atoms, and to use these tools in the study of catalytic processes, with the overall objective of gaining an understanding of the catalytic process which could be used to design more efficient catalysts. The main catalytic system of interest was the combustion of hydrogen on platinum surfaces. Under this project, a flexible Dirac-Hartree-Fock (DHF) program has been developed, a code to calculate DHF correlation energies at the second-order Moeller-Plesset perturbation (PP2) level is almost complete, and code to include correlation at the MCSCF and MCSCF/MP2 level is planned. The tools so far developed have been validated and used to calibrate some more approximate methods, and applied to investigate the importance of relativistic effects in the bonding of hydrogen to platinum.

AN ALTERNATIVE ASSESSMENT OF SECOND-ORDER CLOSURE MODELS IN TURBULENT SHEAR FLOWS Final Report
Charles G. Speziale (Boston Univ., MA.) and Thomas B. Gatski Mar. 1994 19 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-194881; ICASE-94-10; NAS 1.26:194881) Avail: CASI HC A03/MF A01

The performance of three recently proposed second-order closure models is tested in benchmark turbulent shear flows. Both homogeneous shear flow and the log-layer of an equilibrium turbulent boundary layer are considered for this purpose. An objective analysis of the results leads to an assessment of these models that stands in contrast to that recently published by other authors. A variety of pitfalls in the formulation and testing of second-order closure models are uncovered by this analysis.

DETERMINATION OF PRESSURE RESPONSE TIMES FOR GASEOUS FLOW IN A TUBE Ph.D. Thesis
Scott A. Baune 1993 101 p
(AD-A275274; AFIT/CI/CIA-93-1170) Avail: CASI HC A06/MF A02

The motivation for determining the response time for a pressure regulator to adjust the pressure at an area of interest located at the end of a long

tube may be due to several reasons. One of these is the possibility that the regulator cannot be conveniently controlled from a more desirable position closer to the area of interest. Another reason to place to place the regulator a long distance from the area of interest might be to avoid high pressure lines over a prolonged distance. Consider the proposed propulsion system for a microgravity experiment located in the Shuttle car bay. The regulator is controlled electronically so the ability to reduce the amount of electrical wiring will increase system reliability. Furthermore, Shuttle safety requirements demand that high pressure lines be tested for space worthiness, thus placement of the regulator close to the propeliant source may eliminate the presence of these high pressure lines. LONG-WAVELENGTH ASYMPTOTICS OF UNSTABLE CROSSFLOW MODES, INCLUDING THE EFFECT OF SURFACE CURVATURE
Meelan Choudhari Apr. 1994 43 p
(Contract NAS1-19299; RTOP 538-05-15-03)
(NASA-CR-4579; NAS 1.26:4579) Avail: CASI HC A03/MF A01

Stationary vortex instabilities with wavelengths significantly larger than the thickness of the underlying three-dimensional boundary layer are studied with asymptotic methods. The long-wavelength Rayleigh modes are locally neutral and are aligned with the direction of the local inviscid streamline. For a spanwise wave number Beta much less than 1, the spatial growth rate of these vortices is O(Beta(exp 3/2)). When Beta becomes O(R(exp -1/7)), the viscous correction associated with a thin sublayer near the surface modifies the inviscid growth rate to the leading order. As Beta is further decreased through this regime, viscous effects assume greater significance and dominate the growth-rate behavior. The spatial growth rate becomes comparable to the real part of the wave number when Beta = O(R(exp -1/4)). At this stage, the disturbance structure becomes fully viscous-inviscid interactive and is described by the triple-deck theory. For even smaller values of Beta, the vortex modes become nearly neutral again and align themselves with the direction of the wall-shear stress. Thus, the study explains the progression of the crossflow-vortex structure from the inflectional upper branch mode to nearly neutral long-wavelength modes that are aligned with the wall-shear direction. A NEW FLUX-CONSERVING NUMERICAL SCHEME FOR THE STEADY, INCOMPRESSIBLE NAVIER-STOKES EQUATIONS
James R. Scott Apr. 1994 49 p
(RTOP 505-62-52)
(NASA-TM-106520; E-8642; NAS 1.15:106520) Avail: CASI HC A03/MF A01

This paper is concerned with the continued development of a new numerical method, the space-time solution element (STS) method, for solving conservation laws. The present work focuses on the two-dimensional, steady, incompressible Navier-Stokes equations. Using first an integral approach, and then a differential approach, the discrete flux conservation equations presented in a recent paper are rederived. Here a simpler method for determining the flux expressions at cell interfaces is given; a systematic and rigorous derivation of the conditions used to simulate the differential form of the governing conservation law(s) is provided; necessary and sufficient conditions for a discrete approximation to satisfy a conservation law in E2 are derived; and an estimate of the local truncation error is given. A specific scheme is then constructed for the solution of the thin airfoil boundary layer problem. Numerical results are presented which demonstrate the ability of the scheme to accurately resolve the developing boundary layer and wake regions using grids which are much coarser than those employed by other numerical methods. It is shown that ten cells in the cross-stream direction are sufficient to accurately resolve the developing airfoil boundary layer. Author (revised)

RNS OPTIMIZATION PROCEDURE FOR THREE-DIMENSIONAL COMPOSITE VELOCITY MULTI-BLOCK APPLICATIONS Ph.D. Thesis
Hussain Mohamed Hasa Almahroos 1992 215 p
Avail: Univ. Microfilms Order No. DA9313812

RNS analysis of the composite velocity formulation has been applied for three dimensional flows. A consistent coupled strongly implicit procedure has been used to solve the coupled system of equations in general nonorthogonal coordinate system. Different forms of contravariant momentum balances have been examined. A multiblock analogy and optimization strategies have been implemented and are presented. Three dimensional subsonic and transonic, viscous-inviscid interacting flows over afterbody configurations have been evaluated. Laminar and turbulent flow solutions, with and without regions of recirculation and shock wave boundary layer interaction, are presented. Three dimensional flows over multiple body configurations are also presented. Dissert. Abstr.

MODELS FOR VIBRATION-DISSOCIATION COUPLING IN HIGH-TEMPERATURE GASES Ph.D. Thesis
David Albert Gonzales 1993 199 p
Avail: Univ. Microfilms Order No. DA9323408

Nonequilibrium conditions are expected in the flowfields about high speed, high altitude research vehicles. These conditions may be found in regions of rapid compression and rapid expansion in the flowfield. The impact of nonequilibrium effects on such quantities as heat transfer rate and pressure distribution is not clear. This is due in part to the lack of reliable theoretical models with which to predict nonequilibrium processes in high temperature gases. Accurate computational chemistry techniques cannot be used for engineering analyses because they are prohibitively expensive. The focus of this research is on the development of engineering models that suitably reproduce the elaborate computational chemistry results with far greater efficiency. Models are presented which represent both microscopic and macroscopic processes. At the microscopic level, the N-state approximation of Rapp and coworkers is extended to compute velocity dependent inelastic and dissociative transition probabilities for atom-diatom and diatom-diatom collisions. Nitrogen atoms and diatoms are considered in this part of the study and an anharmonic model of the diatom is used. Dissociated product states are modeled by dividing the continuum into discrete states. The acceleration scheme of Secrest is applied to the N-state method and preliminary calculations on the simpler H2-He collision system show order of magnitude increases in efficiency. The N-state approximation is seen to be more accurate than currently used first order theories. At the macroscopic level, master equation simulations are performed. A new model for the state-specific dissociative rate coefficient is presented and validated. The present results are compared to published dissociative cross sections for the para-H2-Ar collision system as computed by the quasiclassical trajectory (QCT) technique. In order to make the comparison consistent, all inelastic rate coefficients used in the master equation are scaled to published inelastic QCT results. The present model is seen to reproduce the more sophisticated dissociative QCT cross sections to within a factor of two in general. The master equation results also indicate that the most significant contribution to the average dissociative rate coefficient comes from the low-to-mid vibrational levels. Similar results have been obtained by other researchers from more expensive detailed computations. Dissert. Abstr.

EVOLUTION OF THE LARGE-SCALE VORTICES IN TURBULENT MIXING-LAYERS Ph.D. Thesis
Slim Aissi 1992 197 p
Avail: Univ. Microfilms Order No. DA9308260

The evolution of the large-scale vortices in turbulent mixing layers was investigated both theoretically and experimentally. In the theoretical study, a novel approach was used to model the dynamics of the large-scale

vortices. The model accounts for the amalgamation processes as well as the advection of the vortices between the amalgamations. The vortices are characterized by the non-dimensional parameter xi is equivalent to lambda/x at formation, where lambda is the wavelength of the vortex and x is its downstream location at formation. The evolution of xi from one vortex generation to the next was investigated and modeled. The resulting equation could be viewed as the first-return map of a nonlinear dynamical system. Such a deterministic model exhibits a wide range of dynamical behavior and the dynamical states were explored as a function of a defined control parameter a. The value of the parameter a for a turbulent mixing layer was obtained using the statistical theory of the large-scale vortices discussed by Bernal. The picture of the randomization of the large-scale vortices that emerged from the theoretical study is a stable, persistent oscillation of the strengths of the vortices around an equilibrium value. This randomization process was found to increase whenever neighboring vortices of different strengths exist in the mixing layer. Other factors that change the randomization process are also discussed. In order to obtain a better understanding of the evolution of the large-scale vortices during their lifespan an experimental study was performed. This study was based on flow visualization and Particle Image Velocimetry (PIV) measurements. The PIV results showed that small vortices were highly stretched during their lifespan and that their peak core vorticity dropped as they convected. Flow reversal and positive vorticity (with negative vorticity being in the vortex cores) were measured in the neighborhood of the large-scale vortices near the jet exit. In addition, a considerable amount of three-dimensionality in the braid regions was observed at the early stages of a vortex lifespan.

FORCED GENERATION OF SOLITARY WAVES IN A ROTATING FLUID AND THEIR STABILITY Ph.D. Thesis

Wooyoung Choi 1993 129 p

Avail: Univ. Microfilms Order No. DA9325345

The primary objective of this graduate research is to study forced generation of solitary waves in a rotating fluid and their stability properties. For axisymmetric flow of a non-uniformly rotating fluid within a long cylindrical tube, an analysis is presented to predict the periodic generation of upstream-advancing vortex solitons by axisymmetric disturbance steadily moving with a transcritical velocity as a forcing agent. The phenomenon is simulated using the forced Korteweg-de Vries (fKdV) equation to model the amplitude function of the Stokes stream function for describing this family of rotating flows of an inviscid and incompressible fluid. The numerical results for the weakly nonlinear and weakly dispersive wave motion show that a sequence of well-defined axisymmetrical recirculating eddies is periodically produced and emitted to radiate upstream of the disturbance, soon becoming permanent in the form as a procession of vortex solitons, which we call vortons. Two primary flows, the Rankine vortex and the Burgers vortex, are adopted to exhibit in detail the process of producing the upstream vortons by the critical motion of a slender body moving along the central axis, with the Burgers vortex being found the more effective of the two in the generation of vortons. To investigate the evolution of free or forced waves within a tube of non-uniform radius, a new forced KdV equation is derived which models the variable geometry with variable coefficients. A set of section-mean conservation laws is derived specially for this class of rotational tube flows of an inviscid and incompressible fluid, in both differential and integral forms. A new aspect of stability theory is analyzed for possible instabilities of the axisymmetric solitary waves subject to non-axisymmetric disturbances. The present linear analysis based on the model equation involving the bending mode shows that the axisymmetric solitary wave is neutrally stable with respect to small bending mode disturbances. To study nonlinear interactions between the axisymmetric mode and bending mode, a new model is derived which consists of two coupled equations for disturbances of the two modes. The numerical results of the coupled equations show that the primary axisymmetric soliton appears to maintain its own entity, with some oscillations of its amplitude and an undular tail, inferring an interchange of energy between the two modes, when subject to small non-axisymmetric perturbations. Dissert. Abstr.

SPHERICAL MODEL FOR TURBULENCE Ph.D. Thesis

Chung-Yu Mou 1993 133 p

Avail: Univ. Microfilms Order No. DA9325370

A new set of models for homogeneous, isotropic turbulence is considered in which the Navier-Stokes equations for incompressible fluid flow are generalized to a set of N coupled equations in N velocity fields. It is argued that in order to be useful these models must embody a new group of symmetries, and a general formalism is laid out for their construction. The work is motivated by similar techniques that have had extraordinary success in improving the theoretical understanding of equilibrium phase transitions in condensed matter systems. The key result is that these models simplify when N is large. The so-called spherical limit, N approaches infinity, can be solved exactly, yielding a closed pair of nonlinear integral equations for the response and correlation functions. These equations, known as Kraichnan's Direct Interaction Approximation (DIA) equations, are, for the first time, solved fully in the scale-invariant turbulent regime, and the implications of these solutions for real turbulence (N = 1) are discussed. In particular, it is argued that previously applied renormalization group techniques, based on an expansion in the exponent, y, that characterizes the driving spectrum, are incorrect, and that the Kolmogorov exponent zeta has a nontrivial dependence on N, with zeta(N approaches infinity) = 3/2. This value is remarkably close to the experimental result, zeta approximately equals 5/3, which must therefore result from higher order corrections in powers of 1/N. Prospects for calculating these corrections are briefly discussed: though daunting, such a calculation would, for the first time, provide a controlled perturbation expansion for the Kolmogorov, and other exponents. Our techniques may also be applied to other nonequilibrium dynamical problems, such as the KPZ equation for interface growth, and perhaps to turbulence in nonlinear wave systems.

METHOD FOR CANCELLING EXPANSION WAVES IN A WAVE ROTOR Patent

Daniel E. Paxson, inventor (to NASA) 29 Mar. 1994 10 p Filed 6 Jul. 1993 Division of US-Patent-Appl-SN-889003, filed 26 May 1992 (NASA-Case-LEW-15218-2; US-Patent-5,297,384; US-Patent-Appl-SN-086581; US-Patent-Appl-SN-889003; US-Patent-Class-60-39.02; Int-Patent-Class-F02C-3/02) Avail: US Patent and Trademark Office

A wave rotor system includes a wave rotor coupled to first and second end plates. Special ports are provided, one in each of the first and second end plates, to cancel expansion waves generated by the release of working fluid from the wave rotor. One of the expansion waves is reflected in the wave rotor from a reflecting portion, and provided to the special port in the second end plate. Fluid present at the special port in the second end plate has a stagnation pressure and mass flow which is substantially the same as that of the cells of the wave rotor communicating with such special port. This allows for cancellation of the expansion wave generated by the release of working fluid from the wave rotor. The special port in the second end plate has a first end corresponding substantially to the head of the expansion wave, and a second end corresponding substantially to the tail of the expansion wave. Also, the special port is configured to continually change along the circumference of the second end plate to affect expansion wave cancellation. An expansion wave generated by a second release of working fluid from the wave rotor is cancelled in a similar manner to that described above using a special port in the first end plate. Preferably the cycle of operation of the wave rotor system is designed so that the stagnation pressure and mass flow of the fluid present at the special ports is the same so that the special ports may be connected by a common duct.

A VORTICITY TRANSPORT CLOSURE METHOD FOR TURBULENT REACTING FLOWS Ph.D. Thesis

Ohbin Kwon 1992 251 p

Avail: Univ. Microfilms Order No. DA9315672

A closure method for variable density turbulent reacting flows is proposed. The vorticity transport theory is herein extended to the case of compressible flows. Specifically, turbulent vorticity and dilatation transport laws have been derived using a Lagrangian analysis of the vorticity transport equation in which velocity-velocity gradient correlations are analyzed keeping compressibility and vortex stretching effects. The complete set of closed

equations includes a new mean dilatation (bar-Theta) transport equation and a turbulent dilatation fluctuation intensity (eta) equation. It is shown that the closure method can also be applied through a primitive variable formulation. In this case, in contrast to the standard eddy viscosity models, the averaged momentum equation has additional terms representing the mechanism of vorticity stretching which is known to be an important boundary layer phenomenon. In addition to the turbulence closure, a turbulent combustion model based on a vorticity dissipation time scale is proposed. To close the turbulent reaction rate expression, a species fluctuation intensity (xi(sub i)) equation is derived as well as species mass balance (bar-Y(sub i)) equation. These equations reflect the rich interaction between turbulence and chemistry. The vorticity transport closure method and the vorticity dissipation combustion model are applied to the internal combustion engine cylinder flow. An implicit finite difference method with full multigrid acceleration is used to solve the governing equations. The calculated results are in good agreement with available experimental data. Dissert. Abstr.

FLOW PAST A CIRCULAR CYLINDER WITH A PERMEABLE WAKE SPLITTER PLATE Ph.D. Thesis
Gregory Scott Cardell 1993 227 p
Avail: Univ. Microfilms Order No. DA9325342

Measurements in the near wake region of a circular cylinder in a uniform flow in the Reynolds number range 2.5 x 10(exp 3) approximately less than or equal to Re approximately less than or equal to 1.8 x 10(exp 4) with permeable splitter plates spanning the wake center plane are presented. Permeability is defined by the pressure drop across the plates, and the relationship between permeability and plate solidity is determined for a set of plates constructed from woven wire mesh, permitting unambiguous characterization of the splitter plates by the solidity. The effects of different solidities on the flow in the near wake are investigated using smoke wire flow visualization, hot-wire anemometry, and measurements of the mean pressure at the cylinder surface, and the results are related to cylinder flow without a splitter plate. Flow visualization results demonstrate that the introduction of low solidity splitter plates does not change the basic near wake structure, and that sufficiently high solidity uncouples the large-scale wake instability from the body, with the primary vortex formation occurring downstream of the separation bubble due to instability of the wake profile. Hot-wire and surface pressure measurements confirm and quantify the flow visualization results, showing that the permeable splitter plates reduce the drag and modify the primary wake frequency. When the solidity is high enough that the wake is convectively unstable, the base pressure is independent of the Reynolds number and solidity. For a wide range of solidities, the same asymptotic value of the Strouhal number is reached at high Reynolds numbers. The relationship between the Strouhal number and the base pressure is discussed. Detailed measurements in the separating shear layers with splitter plates moderating the primary vortex formation show that in the mean the development of the separating shear layers is similar to that of the plane mixing layer. The presence of the splitter plates enhances shear layer development, and it is found that for all solidities the instability amplifies a broad frequency band without discrete spectral features. Turbulent transition in the shear layer and its role in the pronounced Reynolds number dependency of the flow in this Reynolds number range is discussed. Acoustic excitation of the separated shear layers confirms the broad band frequency response of the shear layer instability, and the effect of the driven shear layers on the near wake is investigated. Dissert. Abstr.

DIRECT AND LARGE-EDDY SIMULATIONS OF TURBULENT FLOW IN A SQUARE DUCT Ph.D. Thesis
Ravi Kumar Madabhushi 1993 233 p
Avail: Univ. Microfilms Order No. DA9314909

The fully developed turbulent flow in a square duct has been numerically calculated using both direct (DNS) and largely-eddy (LES) simulation techniques. In the LES calculation, the filtered Navier-Stokes equations were solved using a mixed spectral finite difference procedure in conjunction with a simple eddy viscosity type model for the subgrid stresses. The simulation was conducted at a Reynolds number of 360 based on average friction velocity (5810 based on bulk velocity) and duct width. The simulation was able to predict the existence of turbulence-driven secondary flow and the associated effects on the mean flow and turbulence statistics. The results are in good qualitative agreement with the experimental data available at high Reynolds numbers. The DNS calculation was performed by solving the unsteady, three dimensional Navier-Stokes equations using an efficient and accurate Chebyshev-Fourier collocation procedure. The Reynolds number for this calculation was 260 based on average friction velocity (3850 based on bulk velocity). Distributions of several turbulence statistics (e.g., turbulence stresses, mean-square derivatives, length scales, etc.) in the cross section were computed and discussed in detail. Many of the turbulence statistics along the wall bisector are found to be qualitatively similar to those reported in a channel flow but are generally higher in the square duct flow because of the mean normal velocity along the wall bisector. In the corner region, the characteristics are very different due to the strong influence of the intersecting walls and the secondary flow. A database of instantaneous three dimensional flowfields has been generated and stored for future processing. Dissert. Abstr.

THE h-p ADAPTIVE METHODS FOR INCOMPRESSIBLE VISCOUS FLOW PROBLEMS Ph.D. Thesis
Weihan Robert Wu 1993 222 p
Avail: Univ. Microfilms Order No. DA9323597

The goal of h-p adaptive finite element methods is to obtain the approximate solutions as accurately and quickly as possible and, at the same time, to keep the total cost of computation under control. In this dissertation, we apply h-p adaptive finite element methods to the analysis of complex viscous flow phenomena. These techniques, which are designed to vary simultaneously the mesh size h and the spectral order p of elements, can produce very high resolution of important flow features with relatively small systems of equations and can, under appropriate conditions, deliver exponential rates of convergence. A successful h-p adaptive finite element method requires an efficient data structure, stable incompressible flow solvers for all Reynolds numbers, reliable a posteriori error estimates to measure the accuracy of approximate solutions, and an effective adaptive strategy to seek the best mesh. In this dissertation, we present a family of h-p adaptive finite element methods for solving the time-dependent Navier-Stokes equations in two and three dimensions. We begin by reviewing features of h-p data structures, then discuss the development of stable flow algorithms. An important development presented in this study is a mathematical proof of an a posteriori error estimate for incompressible viscous flows, and an extension of the three-step h-p adaptive strategy to incompressible flow problems. Results indicate that these types of schemes can produce excellent results for incompressible flow simulations at reasonable costs. Dissert. Abstr.

N94-29838 California Inst. of Tech., Pasadena.
NOMINALLY TWO-DIMENSIONAL FLOW ABOUT A NORMAL FLAT PLATE Ph.D. Thesis
Derek Lee Ashton Lisoski 1993 205 p
Avail: Univ. Microfilms Order No. DA9325366

Towing tank and water channel experiments and a vortex element numerical model were used to determine the forces acting on bluff flat plates in nominally two-dimensional flow. Intrinsic (small scale) and extrinsic (large scale) three-dimensional motions in the experimental flow were isolated and their effects studied. Both transient flows starting from rest and steady flow conditions were investigated. A force balance measured unsteady lift and drag while simultaneous LIF flow visualizations imaged the wake structure. Plate aspect ratio, end condition and angle of attack were varied to change large scale three-dimensional motions, while changes in Richardson number (flow stratification) modified three dimensionality intrinsic to the flow. Towing tank experiments indicated that normal plates required sixty to one hundred chord lengths of travel to establish steady vortex shedding. An initial drag peak during acceleration was followed by a drag minimum of C(sub d) approximately equal to 1.3 while the wake was confined to a recirculating bubble. Following the breakdown of this bubble, a region of symmetric flow with C(sub d) approximately equal to 1.6 and no vortex shedding lasted for twenty to thirty chord lengths. During subsequent 'steady-state' shedding, modulation in the vortex shedding amplitude at time scales of five to ten Strouhal periods resulted in a twenty percent fluctuation in the mean level of C(sub d) approximately equal to 2.0. Agreement between three-dimensional experimental and two-dimensional numerical model results was good at early times, indicating experiments were initially two-dimensional. Subsequently, while the wake

was confined to a recirculating bubble, the numerical model gave a drag coefficient C(sub d) approximately equal to 0.9, lower than experiments. Following the breakdown of this closed wake, steady-state drag levels of bar-(C(sub d)) approximately equal to 3.3 were 65 percent higher than experimental values. Dissert. Abstr.

LIQUID ATOMIZATION IN SUPERSONIC FLOWS Ph.D. Thesis
Azzedine Missoum 1993 138 p
Avail: Univ. Microfilms Order No. DA9326598

An experimental investigation of the atomization of a round liquid jet by coaxial, costream injection into a supersonic, Mach 1.5 air flow is reported. Extensive flow visualization was conducted using schlieren/shadowgraph, flash photography, and short duration (ns) laser imaging. The finer details of the jet were revealed when viewed under high magnification with the help of a microscope. The liquid and air pressures were varied individually. Photographic evidence indicates the presence of three regions within the liquid jet: a primary region enclosed by the first shock cell where the primary breakup occurs, a secondary region in which the jet is totally broken because of its interaction with the supersonic wave structure, and a third, subsonic region further downstream. It was found that the breakup mechanism of liquid jets in supersonic airstreams is quite complex. The breakup seems to be initiated by the growth of the turbulent structure on the liquid surface and the subsequent detachment of the three-dimensional structure as fine droplets by the intense shear at the liquid-gas interface. This seems to confirm the boundary layer stripping mechanism. The liquid jet expands into a bubble like formation as it interacts with the first set of waves. Higher liquid injection pressures resulted in higher initial spray angles. The liquid jet displayed a geometry strongly dependent on the pressure distribution resulting from the wave structure present in the supersonic jet. Droplet size and velocity distributions were measured by the P/DPA (Phase/Doppler Particle Analyzer) system. The Sauter Mean Diameter (SMD) was measured at several axial and radial locations at various liquid and air pressures. The SMD shows a decrease with increase in both the air-to-liquid mass flow ratio and the Weber number. The drop size decreased towards the outer edges of the jet. The results lead one to conclude that the coaxial, coflowing configuration is very attractive for atomizing scramjet liquid fuels. Dissert. Abstr.

N94-29843 Cincinnati Univ., OH.
NUMERICAL SOLUTION OF 3-D NAVIER-STOKES EQUATIONS IN VORTICITY-VELOCITY FORM FOR INCOMPRESSIBLE FLOWS Ph.D. Thesis
Yong Huang 1992 273 p
Avail: Univ. Microfilms Order No. DA9313817

The three dimensional Navier-Stokes equations are formulated in vorticity-velocity variables for incompressible flows. The attractive features of this formulation are that the pressure is eliminated from the essential part of the governing equations and the form of the equations remains invariant even in noninertial reference frames. The system of equations consists of the vorticity-transport equation and the kinematic velocity problem. The velocity problem is a constrained system of first-order Cauchy-Riemann type equations in three dimensions. Formulated in generalized curvilinear orthogonal coordinates, the equations are discretized using a finite difference method on a staggered grid. The vorticity-transport equation is integrated by an efficient ADI procedure, whereas the velocity problem is solved by a multigrid method. The pressure, if desired, is obtained by solving the pressure Poisson equation, also with a multigrid method. A shear-driven cavity flow is selected for code validation and for a study of the flow itself. Good agreement with available experimental results is obtained. The unsteady structure of the flow is examined in detail. The vorticity-velocity methodology is then applied to the solution of three dimensional flow over an axisymmetric afterbody. A novel analysis is developed for the governing equations at the centerline in the cylindrical coordinate to treat the 'coordinate singularity.' The evolution of streamwise vorticity, its interaction with the wall, and the wake pressure distribution are analyzed in detail. The results show that the streamwise vortices are attenuated significantly at the wall via interaction with the boundary layer. Further, the circumferential vorticity is strengthened by this interaction. The pressure distribution shows that the streamwise vorticity is instrumental in modifying the pressure field. The flow simulation and analysis have shown that the present vorticity-velocity methodology for three dimensional flows is capable of accurately and efficiently predicting the vortex dynamics of complex flows. LOCAL HEAT TRANSFER IN AN ENCLOSED COROTATING DISK WITH AXIAL THROUGHFLOW Ph.D. Thesis
Soo Yong Kim 1992 258 p
Avail: Univ. Microfilms Order No. DA9315093

Local heat transfer in an enclosed corotating disk with axial throughflow was investigated. The rotating cavity has two plane disks and a cylindrical rim (shroud). The ratio of the rim span to the disk outer radius is 0.4 and the ratio of the disk inner radius to outer radius is 0.25. The objectives of this study are to investigate the effects of axial coolant flow rate, rotational speed, and disk surface temperature on the local heat transfer coefficient distributions inside the disk cavity. Six disk surface heating conditions (BC1, BC2, BC3, BC4, BC5, and BC6) were tested for the axial flow Reynolds numbers between 2500 and 25,000, the rotational Reynolds numbers between 0 and 5.11 x 10(exp 5), and the rotational Grashof numbers between 1.8 x 10(exp 6) and 2.2 x 10(exp 10), respectively. The results showed that the disk cavity local heat transfer coefficients for the nonrotating cavity increase with increasing axial flow Reynolds number. However, the cavity local heat transfer coefficients decrease with increasing rotational Reynolds number and then increase with further increasing rotational Reynolds number. The downstream disk and rim generally have higher Nusselt numbers than the upstream disk. The Nusselt numbers on the upstream disk for BC 4, BC 5, and BC 6 are respectively lower than BC 1 and the Nusselt numbers on the downstream disk for BC 3, BC 5, and BC 6 are respectively lower than BC 1. However, the uneven disk temperature effect on the local Nusselt numbers decrease with decreasing axial Reynolds number and decrease with low rotational Reynolds number (Re(sub r) = 0 to 3.19 x 10(exp 5)) and increase with high rotational Reynolds number (Re(sub r) = 5.11 x 10(exp 5)). The disk cavity Nusselt numbers for BC 1 and BC 2 are comparable. In general, the modified Nusselt numbers (Nu(sub y)) on the upstream and downstream disks of this study are lower than the flat vertical wall natural convection correlations. The Nusselt numbers for Re(sub z) = 25,000 agree well with that of Farthing et al. (Re(sub z) = 2 x 10(exp 4)) except the present data are higher and lower, respectively, near the disk entrance (Gr(sub y) = 10(exp 10)) and near the rim (Gr(sub y) = 10(exp 7)). The averaged Nusselt numbers on the rim increase with increasing rotational Grashof numbers. However, the present rim data are lower than the natural convection correlation from the face down heated plate. Dissert. Abstr.

LARGE EDDY SIMULATION OF SUBSONIC MIXING LAYERS Ph.D. Thesis
Shaw-Ching Sheen 1993 161 p
Avail: Univ. Microfilms Order No. DA9312880

Large eddy simulation is used to study the large-scale structures in a low subsonic mixing layer and their breakdown to small scales. For three dimensional simulations, different finite difference and pseudo-spectral schemes are tested. The (2, 4) MacCormack Scheme developed by Gottlieb and Turkel shows the best overall performance. It is very fast and supplies enough but not excessive artificial dissipation. Though slower than the MacCormack scheme, the pseudo-spectral method has its advantage: high resolution of the high-wavenumber range when an adequate de-aliasing scheme is used. When efficient fast Fourier transform routines are available, this method can be a very good alternative to the MacCormack scheme. Most of the simulations use a modified Smagorinsky-type model. The effect of different models and model constants is also studied. It is found that the two subgrid-scale (SGS) models, the Smagorinsky model and the linear combination model, show significant difference even at the low wavenumber range of the spectra. In the study of three dimensional subsonic temporal mixing layers, it is found that the streamwise vortex tubes play an important role in the transition process. The vortex interaction of the streamwise vortex tubes and undulated spanwise vortex structures proves to be the dominant mechanism in the development of three-dimensionality and the subsequent generation of small-scale motions. In the absence of pairing of the spanwise vortex tubes, this vortex interaction causes uneven distribution of vorticity along the span of the spanwise vortex tubes and the breaking of the large structures. Following the breaking of the spanwise vortex tubes, the secondary streamwise vortex tubes become the dominant vortex

structures. In the case involving pairing, it is found that the relative motion of the spanwise vortex tubes in the pre-pairing process creates much stronger strain rate field between the pairing vortex tubes than the case without pairing. The stronger strain rate field leads to the formation of streamwise vortex tubes with very high vorticity and low induced pressure. Author (revised)

NUMERICAL SOLUTION OF THE TWO-DIMENSIONAL TIME-DEPENDENT INCOMPRESSIBLE EULER EQUATIONS

David L. Whitfield and Lafayette K. Taylor Apr. 1994 65 p

(Grant NAG3-1157)

(NASA-CR-195775; NAS 1.26:195775) Avail: CASI HC A04/MF A01

A numerical method is presented for solving the artificial compressibility form of the 2D time-dependent incompressible Euler equations. The approach is based on using an approximate Riemann solver for the cell face numerical flux of a finite volume discretization. Characteristic variable boundary conditions are developed and presented for all boundaries and in-flow out-flow situations. The system of algebraic equations is solved using the discretized Newton-relaxation (DNR) implicit method. Numerical results are presented for both steady and unsteady flow. Author

AN EXPERIMENTAL INVESTIGATION OF FLOW PATTERNS AND LIQUID ENTRAINMENT IN A HORIZONTAL-TUBE EVAPORATOR Ph.D. Thesis

John Steven Barnhart 1993 257 p

Avail: Univ. Microfilms Order No. DA9314839

An experimental study of two-phase flow patterns and droplet entrainment in a horizontal-tube evaporator was conducted. Measurements were made with serpentine aluminum and glass evaporators with geometries typical of those used for domestic refrigeration. The refrigerant in the majority of tests was R134a, which will replace R12 for refrigeration and automotive air-conditioning in 1995. The phenomenon of primary interest was the nonequilibrium transport of droplets within superheated vapor at the evaporator exit. Of particular concern were substantial variations in the liquid rate with time, and corresponding fluctuations in exit temperature. These variations are due to the formation of slugs which rapidly transport a surplus of liquid toward the exit. A flow loop was constructed to circulate oil-free refrigerant through the evaporator under widely varying conditions. Liquid carry over (expressed as a dimensionless entrained mass fraction, EMF) was measured as a function of inlet quality, heat flux, mass flux, and exit superheat. A laser-based phase/Doppler particle analyzer was used to measure droplet diameters and velocities at the evaporator exit. Tests with three refrigerants over wide ranges of operating conditions revealed time-averaged EMF's of no more than 0.1 percent. Analysis of variance showed exit superheat to have the strongest effect, followed by mass flux, inlet quality, and heat flux. Time-averaged EMF's varied with operating conditions by several orders of magnitude, decreasing with increasing superheat level (due to lower entrainment rates near the exit and more rapid droplet vaporization) and mass flux and inlet quality (due to reduced slug formation). The incidence of slug flow and its effect on evaporator exit conditions were documented in time-resolved experiments, using techniques such as auto- and cross-correlation and Fourier transform. Time-resolved EMF's as high as one percent were observed, as well as sharp reductions in exit superheat of as much as 8 degrees C. The distribution of superheat readings was found to follow a Rayleigh probability density function. This finding will facilitate the use of the superheat reading in control strategies, should it become necessary to actively control refrigerant flow rate. Dissert. Abstr.

A NUMERICAL METHOD FOR CONFINED UNSTEADY FLOWS RELATED TO FLUID-STRUCTURE INTERACTIONS Ph.D. Thesis

Francois Belanger 1991 286 p

(ISBN-0-315-74739-0) Avail: Univ. Microfilms Order No. DANN74739

This thesis elaborates three aspects in the field of flow-induced vibrations associated with annular geometries. A method to find the unsteady fluid forces on a cylinder oscillating in annular turbulent flow is developed by considering the superposition of the turbulent fluctuating quantities on potential flow. The theory is compared with experiments. Then, the unsteady fluid forces acting on the vibrating cylinder walls of nonuniform annular configurations are computed by a method which performs the accurate time integration of the Navier-Stokes equations. It is the extension for unsteady flows of the method of artificial compressibility used for steady flows. A time-discretization of the momentum equation using a three-point-backward implicit scheme is introduced, and the addition of pseudo-time derivative terms to the semidiscretized equations, including artificial compressibility in the continuity equation, allows the use of time-marching solution techniques thereafter. Finally, the integration method used for the Navier-Stokes equations is combined with the equation governing the dynamical behavior of a structure in order to perform the fluid-structure stability analysis of this system in the time domain. NUMERICAL SIMULATION OF RADIATIVE HEAT LOSS IN AN EXPERIMENTAL BURNER

L. D. Cloutman and L. Brookshaw Sep. 1993 23 p Presented at the Fall Meeting of the Western States Section of the Combustion Institute, Menlo Park, CA, 18-19 Oct. 1993

(Contract W-7405-eng-48)

(DE94-002016; UCRL-JC-115048; CONF-931076-1) Avail: CASI HC A03/MF A01

We describe the numerical algorithm used in the COYOTE two-dimensional, transient, Eulerian hydrodynamics program to allow for radiative heat losses in simulations of reactive flows. The model is intended primarily for simulations of industrial burners, but it is not confined to that application. It assumes that the fluid is optically thin and that photons created by the fluid immediately escape to free space or to the surrounding walls, depending upon the application. The use of the model is illustrated by simulations of a laboratory-scale experimental burner. We find that the radiative heat losses reduce the local temperature of the combustion products by a modest amount, typically on the order of 50 K. However, they have a significant impact on NO(x) production. DOE

ALGORITHM AND CODE DEVELOPMENT FOR UNSTEADY THREE-DIMENSIONAL NAVIER-STOKES EQUATIONS

Shigeru Obayashi Apr. 1994 6 p

(Contract NCC2-605)

(NASA-CR-195774; NAS 1.26:195774; MCAT-94-002) Avail: CASI HC A02/MF A01

Aeroelastic tests require extensive cost and risk. An aeroelastic wind-tunnel experiment is an order of magnitude more expensive than a parallel experiment involving only aerodynamics. By complementing the wind-tunnel experiments with numerical simulations, the overall cost of the development of aircraft can be considerably reduced. In order to accurately compute aeroelastic phenomenon it is necessary to solve the unsteady Euler/Navier-Stokes equations simultaneously with the structural equations of motion. These equations accurately describe the flow phenomena for aeroelastic applications. At ARC a code, ENSAERO, is being developed for computing the unsteady aerodynamics and aeroelasticity of aircraft, and it solves the Euler/Navier-Stokes equations. The purpose of this cooperative agreement was to enhance ENSAERO in both algorithm and geometric capabilities. During the last five years, the algorithms of the code have been enhanced extensively by using high-resolution upwind algorithms and efficient implicit solvers. The zonal capability of the code has been extended from a one-to-one grid interface to a mismatching unsteady zonal interface. The geometric capability of the code has been extended from a single oscillating wing case to a full-span wing-body configuration with oscillating control surfaces. Each time a new capability was added, a proper validation case was simulated, and the capability of the code was demonstrated. Author (revised)

SPECTRAL ANALYSIS OF WAVE PROPAGATION IN CONNECTED WAVEGUIDES Ph.D. Thesis

Gopalakrishnan Srinivasan 1992 189 p

Avail: Univ. Microfilms Order No. DA9314083

The spectral element method combined with the Fast Fourier Transform (FFT) is a powerful and versatile tool for analysis of wave propagation problems in connected structures. They are formulated entirely in the

frequency domain and use matrix assembly procedures analogous to the finite element method. This thesis extends the approach to connected structures involving non-uniformities and discontinuities. To handle situations involving deep waveguides, spectral elements are formulated based on the higher order waveguide theories of Timoshenko beam and Mindlin-Herrmann rod. Approximate tapered elements (derived using a frequency domain Ritz method) are formulated to handle situations involving member cross-section variations. For waveguides with embedded discontinuities like cracks and holes, the irregular behavior near the discontinuity is isolated by performing Local/Global analysis via the super spectral element concept. Efficient computation of the super element stiffness is the key to the success of the method and it is addressed directly. The formulated element is verified by comparison with the conventional finite element solution. Some interesting problems involving joints, cracks and holes are solved. One of the distinct advantages of the spectral approach is the capability to perform inverse problems. The concept is demonstrated with some illustrative examples involving multiple boundaries. HIGH-RESOLUTION ALGORITHMS FOR THE NAVIER-STOKES EQUATIONS FOR GENERALIZED DISCRETIZATIONS Ph.D. Thesis
Curtis Randall Mitchell 1992 196 p
Avail: Univ. Microfilms Order No. DA9312878

Accurate finite volume solution algorithms for the two dimensional Navier Stokes equations and the three dimensional Euler equations for both structured and unstructured grid topologies are presented. Results for two dimensional quadrilateral and triangular elements and three dimensional tetrahedral elements will be provided. Fundamental to the solution algorithm is a technique for generating multidimensional polynomials which model the spatial variation of the flow variables. Cell averaged data is used to reconstruct pointwise distributions of the dependent variables. The reconstruction errors are evaluated on triangular meshes. The implementation of the algorithm is unique in that three reconstructions are performed for each cell face in the domain. Two of the reconstructions are used to evaluate the inviscid fluxes and correspond to the right and left interface states needed for the solution of a Riemann problem. The third reconstruction is used to evaluate the viscous fluxes. The gradient terms that appear in the viscous fluxes are formed by simply differentiating the polynomial. By selecting the appropriate cell control volumes, centered, upwind and upwind-biased stencils are possible. Numerical calculations in two dimensions include solutions to elliptic boundary value problems, Ringlebs' flow, an inviscid shock reflection, a flat plate boundary layer, and a shock induced separation over a flat plate. Three dimensional results include the ONERA M6 wing. All of the unstructured grids were generated using an advancing front mesh generation procedure. Modifications to the three dimensional grid generator were necessary to discretize the surface grids for bodies with high curvature. In addition, mesh refinement algorithms were implemented to improve the surface grid integrity. Examples include a Glasair fuselage, High Speed Civil Transport, and the ONERA M6 wing. The role of reconstruction as applied to adaptive remeshing is discussed and a new first order error estimator is presented. Numerical examples of the remeshing procedure include both smooth and discontinuous flows.

HYDRODYNAMIC STABILITY ANALYSIS OF SWIRLING JETS Ph.D. Thesis
Charles Chengzhi Wu 1992 155 p
Avail: Univ. Microfilms Order No. DA9313200

The present work is fundamental in nature and aims to achieve a better understanding of the instability character of swirling jets. Spatial hydrodynamic instabilities of inviscid swirling jets have been investigated theoretically. The hydrodynamic stability analysis has first been applied to an inviscid, incompressible, top-hat jet, with a swirl distribution of solid body rotation and free vortex in and outside the vortex core, respectively. This velocity profile simulates the mean velocity field near the jet exit. The stability analysis has then been extended to inviscid, incompressible, non-top-hat swirling jets, which describe the mean velocity field downstream. Two types of non-top-hat swirling jets have been studied. Type 1 velocity profile is a trailing-vortex with parallel flow assumption. Type 2 velocity profile is based on analytical-experimental solutions with no parallel flow limitation and, hence, is more realistic. It is found that top-hat jets with swirl distribution of Rankine vortex type are spatially unstable in all the excitation modes examined; i.e., m = 0, +/-1, +/-2, +/-3. Amplification rates of top-hat swirling jets are increased monotonically. Helical-mode excitation has little impact on nonswirling, top-hat jets but has a strong influence on swirling jets. The higher the positive helicity, the less unstable is the behavior; the higher the negative helicity, the more unstable the behavior becomes. It is also found that stronger centrifugal effect makes swirling jets less unstable under positive helical-mode excitation, and makes them more unstable under negative helical-mode excitation. Non-top-hat swirling jets are only unstable under excitation modes m = 0, -1, -2, -3 and under small frequency excitations. They become stable as frequency increases. Their amplification rates behave differently than those of top-hat swirling jets with a 'hump' distribution. The trends of helical-mode excitation and centrifugal effect are similar to those of 'top-hat swirling jets.' In general, non-top-hat swirling jets are less unstable than top-hat swirling jets. Combining the results of these two parts, the overall instability character of swirling jets is captured in the stream wise direction. Two comparisons are made between the experimental data and theoretical results for a low intensity swirling jet. The initial growth trend of the fundamental instability wave in the near field is captured. The comparisons also show the limitation of linear, inviscid stability theory. Dissert. Abstr.

THE INSTANTANEOUS CONCENTRATION FIELD IN THE SELF-SIMILAR REGION OF A HIGH SCHMIDT NUMBER ROUND JET Ph.D. Thesis
Minami Yoda 1993 175 p
Avail: Univ. Microfilms Order No. DA9309689

The aim of this work is to characterize the far-field structure of the nearly and fully turbulent (Reynolds number less than or = 5000) round water (high Schmidt number) jet. This thesis describes the acquisition and analysis of three-dimensional concentration data using a laser-induced fluorescence technique. Isoconcentration surfaces are used to deduce the large-scale structure and modal composition of the jet. The evolution of two-dimensional (x-y-t) axial concentration fields in fully turbulent natural, circularly and axially excited water jets is visualized. Large-scale structure is found in the form of 'ridges' on the x-y-t isoconcentration surfaces; they are common and robust, or long-lived. Assuming that these structures correspond to the instability modes predicted by linear theory, and that symmetry arguments can be used to distinguish these modes, cross correlation techniques are used to determine whether these structures are in the axisymmetric and helical modes. Both symmetric (axisymmetric mode) and antisymmetric (helical mode) structures are found in the natural jet; only antisymmetric structures are found in both types of excited jets. The instantaneous three-dimensional (x-y-z) concentration fields of nearly and fully turbulent (Reynolds numbers 1000, 2000 and 4000) natural and circularly excited jets are measured. Large-scale structure, which appears to be present only in fully turbulent jets, is found in the form of axisymmetric 'clumps' of higher concentration jet fluid along the flow direction x. These structures are of a downstream extent approximately equal to the local jet diameter. The antisymmetric two-dimensional images previously thought to be 'slices' of a spiral in three dimensions turn out instead to be slices of a simple sinusoid. This result suggests that the helical instability mode, if present, is in the form of a pair of counter rotating spiral vortex filaments. The local structure of the concentration gradient field is analyzed using critical point concepts. The concentration field is shown to consist of axisymmetric filamentary structures stretched along the axis of symmetry, which tends to be inclined at an angle of +/- 135 deg to x, or the expected intermediate (extensive) strain direction. These results and results from direct numerical simulations suggest that the small-scale flow consists of intense vortex filaments aligned with this direction; these filaments draw in and 'swirl' the passive scalar around their axis, while the strain stretches the scalar along the filament axis. Finally, the scalar dissipation is calculated and visualized. It is shown that much of the mixing in the flow is taking place in a small fraction of the flow volume, in regions that geometrically appear to be convoluted and sheetlike. Dissert. Abstr.

LUNAR BASE HEAT PUMP, PHASE 1 DRAFT Final Report
Jeffrey H. Goldman, A. Harvey, T. Lovell, and David H. Walker Apr. 1994 67 p

(Contract NAS9-18819; FMI Proj. NAS-9614)
(NASA-CR-195211; NAS 1.26:195211; NAS-8819-FM-9614-820) Avail: CASI HC A04/MF A01

This report describes the Phase 1 process and analysis used to select a refrigerant and thermodynamic cycle as the basis of a vapor compression heat pump requiring a high temperature lift, then to perform a preliminary design to implement the selected concept, including major component selection. Use of a vapor compression heat pump versus other types was based on prior work performed for the Electric Power Research Institute. A high lift heat pump is needed to enable a thermal control system to remove heat down to 275K from a habitable volume when the external thermal environment is severe. For example, a long-term lunar base habitat will reject heat from a space radiator to a 325K environment. The first step in the selection process was to perform an optimization trade study, quantifying the effect of radiator operating temperature and heat pump efficiency on total system mass; then, select the radiator operating temperature corresponding to the lowest system mass. Total system mass included radiators, all heat pump components and the power supply system. The study showed that lunar night operation, with no temperature lift, dictated the radiator size. To operate otherwise would require a high mass penalty to store power. With the defined radiation surface, and heat pump performances assumed to be from 40 percent to 60 percent of the Carnot ideal, the optimum heat rejection temperature ranged from 387K to 377K, as a function of heat pump performance. Refrigerant and thermodynamic cycles were then selected to best meet the previously determined design conditions. The system was then adapted as a ground-based prototype lifting temperature to 360K (versus 385K for flight unit) and using readily available commercial-grade components. Over 40 refrigerants, separated into wet and dry compression behavioral types, were considered in the selection process. Refrigerants were initially screened for acceptable critical temperature. The acceptable refrigerants were analyzed in ideal single and two-stage thermodynamic cycles. Top candidates were analyzed assuming realistic component limits and system pressure drops, and were evaluated for other considerations such as safety, environmental impact and commercial availability. A maximum coefficient of performance (COP) of 56 percent of the Carnot ideal was achievable for a three-stage CFC-11 cycle operating under the flight conditions above. The program was completed by defining a control scheme and by researching and selecting the major components, compressor and heat exchangers, that could be used to implement the thermodynamic cycle selected. Special attention was paid to using similar technologies for the SIRF and flight heat pumps resulting in the commercially available equivalent of the flight unit. A package concept was generated for the components selected and mass and volume estimated. Author

LARGE HEAT PUMPS USING CO2 REFRIGERANT
G. Lorentzen 17 Feb. 1993 10 p
(PB94-138773; STF11-A93017) Avail: Issuing Activity (National Technical Information Service (NTIS))

It has been demonstrated in previous reports that carbon dioxide (CO2) is a near ideal refrigerant in every respect, provided that a suitable thermodynamic process to give a competitively low power consumption can be designed. Such a process has been proposed for the use in large heat pumps, where the output has to be supplied to a gliding temperature sink, typically a district heating system. Also CO2 lends itself to the effective recovery of expansion work. It is possible to improve the efficiency and COP of district heating systems with at least 20-25 percent over conventional technology. NTIS

This paper describes work in modeling concentrated liquid-solids flows in pipes. COMMIX-M, a three-dimensional transient and steady-state computer program developed at Argonne National Laboratory, was used to compute velocities and concentrations. Based on the authors' previous analyses, some concentrated liquid-solids suspension flows display shear-thinning rather than Newtonian phenomena. Therefore, they developed a two-phase non-Newtonian power-law model that includes the effect of solids concentration on solids viscosity. With this new two-phase, power-law, solids-viscosity model, and with constitutive relationships for interfacial drag, virtual mass effect, shear lift force, and solids partial-slip boundary conditions at the pipe walls, COMMIX-M is capable of analyzing concentrated three-dimensional liquid-solids flows. NUMERICAL COMPARISON OF CONVECTIVE HEAT TRANSFER AUGMENTATION DEVICES USED IN COOLING CHANNELS OF HYPERSONIC VEHICLES
Jaime J. Maldonado Apr. 1994 28 p
(RTOP 505-70-69)
(NASA-TM-106546; E-8695; NAS 1.15:106546) Avail: CASI HC A03/MF A01

Hypersonic vehicles are exposed to extreme thermal conditions compared to subsonic aircraft; therefore, some level of thermal management is required to protect the materials used. Normally, hypersonic vehicles experience the highest temperatures in the nozzle throat, and aircraft and propulsion system leading edges. Convective heat transfer augmentation techniques can be used in the thermal management system to increase heat transfer of the cooling channels in those areas. The techniques studied in this report are pin-fin, offset-fin, ribbed and straight roughened channel. A smooth straight channel is used as the baseline for comparing the techniques. SINDA '85, a lumped parameter finite difference thermal analyzer, is used to model the channels. Subroutines are added to model the fluid flow assuming steady one dimensional compressible flow with heat addition and friction. Correlations for convective heat transfer and friction are used in conjunction with the fluid flow analysis mentioned. As expected, the pin-fin arrangement has the highest heat transfer coefficient and the largest pressure drop. All the other devices fall in between the pin-fin and smooth straight channel. The selection of the best heat augmentation method depends on the design requirements. A good approach may be a channel using a combination of the techniques. For instance, several rows of pin-fins may be located at the region of highest heat flux, surrounded by some of the other techniques. Thus, the heat transfer coefficient is maximized at the region of highest heat flux while the pressure drop is not excessive. Author

UNSTRUCTURED SPACE-TIME FINITE ELEMENT METHOD OF HEAT CONDUCTION Ph.D. Thesis
Chi-Kyung Kim 1992 115 p
Avail: Univ. Microfilms Order No. DA9313053

A space-time finite element method is presented for solving heat transfer involving a moving heat source so that small time steps can be used in areas of large time rates of change of temperature. The weighted residual process is used to formulate a finite element method in a space-time domain based upon the discontinuous Galerkin method. Most of the early works on the discontinuous Galerkin method for ordinary differential equations have been mathematically oriented. Based on the numerical success of the time-discontinuous Galerkin method for ordinary differential equations, this research extends the method to problems involving second-order parabolic equations, e.g. transient heat conduction. The focus is on adaptively controlling the time step in a one-dimensional moving

heat source simulation. Utilizing the efficiency of finite elements by choosing a finite element mesh in the space-time domain, the finite element mesh has been adjusted to steep gradients of the solution with respect to the space and time variables. Dissert. Abstr.

PREDICTION OF FLUID FLOW AND HEAT TRANSFER IN INTERNALLY FINNED TUBES Ph.D. Thesis
Mohammed Youssef Al-Hashem 1993 113 p
Avail: Univ. Microfilms Order No. DA9324418

Fully developed fluid flow and heat transfer characteristics in internally finned tubes were investigated. Both laminar and turbulent flows were considered. Longitudinal fins of trapezoidal profile integrally attached to the tube wall are equally spaced circumferentially in the tube. The assumption of axially constant heat flux per unit length was applied. The tube wall temperature was assumed to be circumferentially uniform at any cross section but varies axially with the change of the bulk temperature. With a fin of finite conductivity, the temperature varies along the fin height. The influence of the ratio of the fin to fluid thermal conductivity ratio, K(sub fin)/K(sub fluid), was investigated for both laminar and turbulent flows. Results for laminar flow case were presented for a fin height to tube radius ratio H/R, ranging from 0.2 to 0.9; the number of fins, NFIN, was varied from 6 to 30; and fin half angles, beta, were varied from 1.5 to 3 degrees. It was found that for any specified geometry the Nusselt number is influenced by a single parameter, K(sub fin)/K(sub fluid). A mixing length model developed by Ivanovic and Patankar was used to predict the results for turbulent fluid flow. Results were presented for a range of fin height to tube radius, H/R, which was varied from 0.2 to 0.4; NFIN ranged from 6 to 22; beta was selected as 1.5 and 3 degrees; and Reynolds number, Re, varied from 10,000 to 100,000. Predicted results for isothermal fins were shown to be in agreement with other researchers. The results provide extensive information on the influence of the fin to fluid thermal conductivities ratio. It is evident from the results that the assumption of isothermal fins is an inaccurate one, especially at high Reynolds number and either high H/R or low K(sub fin)/K(sub fluid) ratio. Dissert. Abstr.

THREE-DIMENSIONAL FLOW CHARACTERISTICS DOWNSTREAM OF A BLADE ENDWALL CORNER Ph.D. Thesis
AbdulKarim A. J. Abd Altaii 1993 231 p
Avail: Univ. Microfilms Order No. DA9325064

The flow downstream of the corner formed by an airfoil and a flat plate was investigated experimentally. The region for this study was simulated by attaching two uncambered, unswept NACA 65-015 airfoils on either side of a flat plate. The airfoils had a semicircular leading edge. The initial 7 cm of the leading edge of the flat plate was artificially roughened by gluing a strip of sand paper to promote a thicker turbulent boundary layer. Free stream turbulence of the order of 1.5 percent was introduced, by inserting a combination of two grids, to avoid a separation bubble on the airfoil. Measurement techniques employed in this investigation were: surface flow visualization, conventional pitot-static probe, the Preston tube, and the five hole probe. Surface flow visualization defined the boundaries of the vortex system and provided information on the direction and the magnitude of the wall shear stress. Local wall shear stress was measured using specially constructed Preston tubes. The characteristics of the Preston tube were also investigated. Total and static pressure distribution measurements, including the flat plate surface, were made using a pitot-static probe. The five hole probe was used, in the seminulling mode, to collect data on the three components of mean velocity. The measurements were carried out at eight axial stations downstream of the trailing edge of the airfoil. At every axial location downstream of the trailing edge of the airfoil forming the corner with a flat plate, a single dominant horseshoe vortex was identified which persisted more than one chord length downstream. A smaller and weaker corner vortex was also identified. It dissipated and ceased to exist by a downstream axial location of approximately 0.2C. There was no evidence of stress induced vortices in the region of this investigation. The secondary flow system redistributes the mean flow momentum and distorts total pressure profiles and contours. In planes parallel to the flat plate, total pressure profiles were found to be higher than the undisturbed two dimensional boundary layer at that height. Surface static pressure was found to be at its maximum at the airfoil trailing edge location and it decreased in both the downstream and transverse directions. There was no significant static pressure variation in the spanwise direction. Dissert. Abstr.

THE EFFECT OF A WAVY BOUNDARY ON TURBULENT FLOW Ph.D. Thesis
John Dale Hudson 1993 195 p
Avail: Univ. Microfilms Order No. DA9329065

Two-component velocity measurements were obtained near a solid wavy boundary. The resulting database includes a variety of flow conditions including two wave steepnesses and a large range of flow rates. Detailed analyses of one of these flows are given. These serve as a reference point for determining the effects of wave steepness and flow rate. The contributions of this study of the effect of a wavy boundary on turbulent flow are fourfold. First, the outer flow is found to be insensitive to the method of turbulence generation near the wavy surface. Second, the turbulence in the near wall region is found to originate from shear layers which separate from the wave crests. The turbulent stresses and turbulent energy production of the flow are, largely, associated with these layers. Third, detailed information on the Reynolds stress is provided which should help in understanding important flow systems and should provide a challenge of current general methods for computing turbulent fields. Finally, velocity measurements were used to map out the pressure field within the flowing system. Dissert. Abstr.

A SINGLE-FLUID, SELF-CONSISTENT FORMULATION OF PARTICLE TRANSPORT AND FLUID DYNAMICS Ph.D. Thesis
Lance Lee Williams 1993 138 p
Avail: Univ. Microfilms Order No. DA9328566

I present a formulation of fluid dynamics that is consistent with particle transport and acceleration. This formulation consists of two parts: a transport equation that describes the evolution of a particle distribution function in terms of a fluid velocity in which the distribution is embedded, and an equation for the fluid velocity that involves integrals of the distribution function. The motivation for this work is to provide a formalism for calculating the effect of particle acceleration on the flows of typical astrophysical plasmas. It is shown that the equation to be solved simultaneously with the transport equation is just the momentum equation for the system, and that the number and energy equations are implicit in the transport equation. There is no restriction on the energies of particles constituting such systems. Connections are made to the cosmic-ray transport equation, two-fluid models of cosmic ray/thermal gas interaction, and self-consistent Monte Carlo models of particle acceleration at parallel shocks. The formalism is developed for non-relativistic flow speeds. It is assumed that particle distributions are nearly isotropic in the fluid frame, an assumption that is generally valid in space plasmas. It is assumed that particle scattering mean-free-paths are much less than the length scales associated with changes in the fluid velocity or particle distribution. Dissert. Abstr.

THE ENHANCEMENT OF COMPRESSIBLE TURBULENT MIXING VIA STREAMWISE VORTICITY Ph.D. Thesis
Jonathan Wayne Naughton 1993 257 p
Avail: Univ. Microfilms Order No. DA9326911

Compressible turbulent mixing layers have been studied in great detail in an attempt to understand and control the mechanisms governing them. Although much has been learned from these studies, attempts to significantly increase the mixing of the two component streams have been largely unsuccessful. Based upon promising results from subsonic swirling-jet studies, the present work was initiated to demonstrate conclusively the effect of streamwise vorticity on the mixing of co-flowing supersonic streams. A vortex injector was designed in order to produce a supersonic vortical primary stream along the axis of the wind tunnel test section. These flowfields are imaged by the planar laser scattering (PLS) technique, while the vortices' strengths are quantified using intrusive probes and laser Doppler velocimetry (LDV). In addition, the PLS seed particles are shown to represent faithfully the dynamics of the turbulent swirling flow. The results of analyzing the PLS images indicate that an enhancement in mixing rate of up to 60% for the present test cases is possible through the addition of streamwise vorticity. Furthermore, the degree of mixing enhancement scales with the

vortex strength and appears to be independent of the degree of compressibility of the mixing layer. Analysis of the instantaneous turbulent structure suggests that the observed increase in mixing is due to a modification of large-scale turbulent structures in the mixing layer.

A NEW ORTHOGONAL DECOMPOSITION METHOD FOR TURBULENT FLOWS Ph.D. Thesis
Ali Kodal 1993 159 p
Avail: Univ. Microfilms Order No. DA9319564

This thesis deals with the decomposition of general turbulent flow variables into their mean, organized, and turbulent parts. After decomposition, equations of fluid motion can then be devised for each component of flow. While numerous techniques have been proposed for identifying organization in fluid motion, they are typically statistical rather than physical and do not necessarily provide desirable properties such as orthogonality between decomposed components. The aim of this thesis is to explore a new technique for identifying organization in turbulent fluid flow which incorporates physical information, makes efficient use of measured data, and can be applied to turbulent flows with complexities such as nonstationarity and inhomogeneity. In this study, attributes of stationary steady and unsteady turbulent flows are first considered. A new frequency domain filtering technique is then developed to make an orthogonal decomposition of turbulent flow into organized and residual turbulent components. The technique is then adapted for applications of nonstationary and inhomogeneous data series in one and two dimensions. Performance evaluations and comparisons between this new technique and existing ones are made. From these evaluations, this new technique is shown to give better performance than existing ones for stationary and selected nonstationary turbulent flow data series and shows promise as an adaptive tool for identifying organization in turbulence. Dissert. Abstr.

THREE DIMENSIONAL COMPRESSIBLE TURBULENT FLOW COMPUTATIONS FOR A DIFFUSING S-DUCT WITH/WITHOUT VORTEX GENERATORS Ph.D. Thesis
Soo Yong Cho 1993 216 p
Avail: Univ. Microfilms Order No. DA9321875

Numerical investigations on a diffusing S-duct with/without vortex generators and a straight duct with vortex generators are presented. The investigation consists of solving the full 3-D unsteady compressible mass averaged Navier-Stokes equations. An implicit finite volume lower-upper time marching code (RPLUS3D) has been employed and modified. A 3-D Baldwin-Lomax turbulence model has been modified in conjunction with the flow physics. A model for the analysis of vortex generators in a fully viscous subsonic internal flow is evaluated. A vortical structure for modeling the shed vortex is used as a source term in the computation domain. The injected vortex paths in the straight duct are compared with the analysis by two kinds of prediction models. The flow structures by the vortex generators are investigated along the duct. Computed results of the flow in a circular diffusing S-duct provide an understanding of the flow structure within a typical engine inlet system. These are compared with the experimental wall static-pressure, static-, and total-pressure field, and secondary velocity profiles. Additionally, boundary layer thickness, skin friction values, and velocity profiles in wall coordinates are presented. In order to investigate The effect of vortex generators, various vortex strengths are examined. The total-pressure recovery and distortion coefficients are obtained at the exit of the S-duct. The numerical results clearly depict the interaction between the low velocity flow by the flow separation and the injected vortices. Dissert. Abstr.

An electromagnetic accelerator in the form of a linear electric motor (LEM) has been designed to achieve controlled acceleration profiles of a carriage containing hydrodynamically unstable fluids for the investigation of the development of turbulent mix. The Rayleigh-Taylor instability is investigated by accelerating two dissimilar density fluids using the LEM to achieve a wide variety of acceleration and deceleration profiles. The acceleration profiles are achieved by independent control of rail and augmentation currents. A variety of acceleration-time profiles are possible including: (1) constant, (2) impulsive and (3) shaped. The LEM and support structure are a robust design in order to withstand high loads with deflections and to mitigate operational vibration. Vibration of the carriage during acceleration could create artifacts in the data which would interfere with the intended study of the Rayleigh-Taylor instability. The design allows clear access for diagnostic techniques such as laser induced fluorescence radiography, shadowgraphs and particle imaging velocimetry. Electromagnetic modeling codes were used to optimize the rail and augmentation coil positions within the support structure framework. Results of contemporary studies for non-arcing sliding contact of solid armatures are used for the design of the driving armature and the dynamic electromagnetic braking system. A 0.6MJ electrolytic capacitor bank is used for energy storage to drive the LEM. This report will discuss a LEM design which will accelerate masses of up to 3kg to a maximum of about 3000g(sub o), where g(sub o) is accelerated due to gravity. DOE

(PB94-1255722-U; NLR-TP-92222-U; ETN-94-95583) Avail: CASI HC A03

An eigenvalue analysis is developed for a Euler method, using cell centered central differences and a Runge-Kutta time integration method, and applied to a quasi one-dimensional nozzle flow. An accurate estimation of the convergence behavior is made, based on the largest amplification factor of all eigenvalues of the Jacobian. This analysis method is used to investigate the influence of boundary conditions and numerical parameters on the convergence behavior. ESA

EULER RESULTS OF THE ISNaS COMPRESSIBLE MULTI-BLOCK FLOW SOLVER
W. Wagenaar and M. E. S. Vogels 30 Oct. 1992 24 p Presented at the 5th ISNaS Symposium, Twente, Netherlands, 5-6 Nov. 1992 Sponsored by Ministry of Education and Sciences, and Ministry of Transport and Public Works Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B179299; NLR-TP-92443-U; ETN-94-95963) Avail: CASI HC A03

The development of a multizone multiblock Navier-Stokes flow solver, directed towards the multielement airfoil application, for the ISNaS, an Information System for flow simulation based on the Reynolds averaged Navier-Stokes equations, is addressed. In the pipeline of the flow solver special editors support the input preparation. The development and test approach for the Euler computational kernel are described. Euler results for the flow solver are discussed to the level of verification. It is demonstrated that the flow solver gives flow results for the multielement airfoil application. The starting point of the validation of the flow solver was reached. Further development will involve validation, performance acceleration, and addition of new models, algorithms, and boundary types. DEVELOPMENT AND APPLICATION OF PARTICLE IMAGE VELOCIMETRY IN HIGH-SPEED SEPARATED FLOW: TWO-DIMENSIONAL BASE CAVITIES Ph.D. Thesis
Michael Joseph Molezzi 1993 197 p
Avail: Univ. Microfilms Order No. DA9329114

A new particle image velocimetry (PIV) system has been developed to obtain two-dimensional instantaneous velocity data over a planar region in high-speed separated flows for the quantitative analysis of turbulent and unsteady flow structures. This PIV system is the first of its type to incorporate sub-micron seed particles and birefringent image shifting for the resolution of flow velocity in separated regions. The system was also developed with improved in-plane spatial resolution over previous high-speed flow PIV applications by using a 1.0 sq mm interrogation region (in flowfield dimensions) for each independent velocity measurement. The system has been proven in preliminary experiments using a simple low-speed round jet flow and had been validated for accuracy with both known-displacement simulated PIV photographs and uniform flow experiments at Mach 0.5 (170 m/s) for comparison to pressure and laser Doppler velocimeter (LDV) data. The PIV system was also used in a study of the near-wake structure of a two-dimensional base in subsonic flow. This application was chosen in order to determine the fluid dynamic mechanism of the observed base drag reduction in the presence of a base cavity. Experiments were done over a range of freestream Mach numbers up to 0.8, including local flowfield velocities up to 300 m/s. Effects of the base cavity on the von Karman vortex street wake were found to be related to the expansion and diffusion of vortices near the cavity, although the effects are of small magnitude and no significant change of the vortex formation location or path was observed. The base cavity effects are also less significant at higher freestream velocities due to the formation of vortices further downstream from the base. The base cavity drag reduction was found to be mainly due to the displacement of the base surface to a location upstream of the low-pressure wake vortices, with only a slight modification in the vortex street itself. Dissert. Abstr.

THE EFFECT OF PRESSURE GRADIENT ON THE STRUCTURE OF AN EQUILIBRIUM TURBULENT BOUNDARY LAYER Ph.D. Thesis
Ting-Kwo Lei 1993 157 p
Avail: Univ. Microfilms Order No. DA9328854

Hot-wire anemometry was used to study the effect of adverse pressure gradient on the large-scale structures of equilibrium turbulent boundary layers. A previously existing zero-pressure gradient wind tunnel was modified into an adverse-pressure gradient wind tunnel, which had the capability of creating designated adverse-pressure gradient equilibrium turbulent boundary layer flows. The range of the equilibrium parameter beta was from 0.0 to 1.8 along a 1.50 m long test section of the wind tunnel. Computer programs were developed to predict the geometric shape of the test section for an equilibrium adverse-pressure gradient turbulent boundary layer flow. The numerical prediction of the test section geometry was found to be satisfactory and a substantial effort was saved in the establishment of an equilibrium boundary layer. Three equilibrium boundary layer flows at values of beta = 0.0, 0.8, and 1.8, which respectively represents zero, mild, and strong adverse pressure gradient, were established and were found to be suitable for turbulence structure measurements. Space-time correlation measurements were carried out to determine the convection velocities and inclination angles of the large-scale structures for the three different pressure gradient cases. The convection velocity measurements were performed at various heights which ranged form y(sup +) = 225 to 525 for each beta value. It was found that, within the range of height of the measurements, the convection velocity was independent of height In the case of the strong adverse-pressure gradient flow, the convection velocity was observed to be much lower than the convection velocity observed in the case of zero-pressure gradient. In the case of the mild-pressure gradient flow, it was observed that the pressure gradient effect on the convection velocity was negligible as compared to the zero-pressure gradient case. The inclination angle in the case of strong-pressure gradient case was found to be much greater than that observed in the case of zero-pressure gradient case. The pressure gradient effect on the inclination angle was observed to be negligible in the case of mild ad verse-pressure gradient case.

MIXED EULERIAN-LAGRANGIAN FINITE ELEMENT SOLUTIONS OF UNSTEADY FLOW AND FLUTTER IN TRANSONIC CASCADE Ph.D. Thesis
Chingteng Hsiao 1993 212 p
Avail: Univ. Microfilms Order No. DA9319918

Unsteady flow and flutter phenomena of turbomachinery cascades operating in the transonic regime are explored by a new numerical approach. The two dimensional unsteady Euler equations are used to model the transonic cascade flows, and the cascade blades are modeled as thin plates. To minimize the discretization incompatibility, both the fluid and the solid domains are discretized using finite element procedures. The Rayleigh-Ritz finite element formulations are employed in the structural discretization while the Galerkin finite element procedure is used in the fluid discretization. As is customary, the discretized equations of the cascade blades are described in purely Lagrangian coordinates. However, in order to take care of the time-varying boundary conditions effectively, the mixed Lagrangian-Eulerian description is used in the fluid domain. The fluid and the structural models are coupled by introducing a channel theory, which is equivalent to a strip theory in the classical sense. In this procedure several two dimensional aerodynamic solvers are combined with one three dimensional structural solver to form a quasi three dimensional aeroelastic system. The whole system is marched toward in time using an explicit four-stage Runge-Kutta scheme to obtain the time domain solutions. Steady and unsteady transonic flow results are both presented. The current finite element Euler solutions show very good agreement with available finite volume Euler solutions. Free vibration analyses of nonrotating and rotating blades using the present finite element model with 80 degrees of freedom have been carried out. The computed natural frequencies and mode shapes are comparable to other finite element and Rayleigh-Ritz results. Aeroelastic responses of several cascade configurations in different transonic flow fields are investigated using either a typical section model or the present quasi three dimensional model. These analyses demonstrate that the current full blade structure formulation can handle flutters involving higher modes and hence have a better estimation of the flutter boundary.

NUMERICAL SIMULATION OF A CONDENSER IN TWO-PHASE HEAT TRANSPORT SYSTEMS: A FEASIBILITY STUDY
A. A. tenDam and J. I. vandeBerg 30 Apr. 1992 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B173650; NLR-TP-92081-U; ETN-94-95572) Avail: CASI HC A03

The numerical simulation of a mathematical model of a condenser is discussed. This mathematical model is part of an approach to model and scale two phase heat transport systems. The model of the condenser is reformulated to a model that is suitable for a numerical discussion. The result is a model that is represented by an implicit nonlinear differential/algebraic equation. One numerical solution procedure is discussed. Test cases are defined and simulation studies are conducted with several working fluids and under varying gravity conditions. The simulation results show that the approach taken is suitable to obtain the behavior of a condenser. ESA

AN EXPERIMENTAL STUDY OF NONLINEAR WAVE COUPLING AND ENERGY TRANSFER CHARACTERIZING THE TRANSITION OF A PLANAR JET SHEAR LAYER Ph.D. Thesis

Huan Chang Chu 1993 282 p
Avail: Univ. Microfilms Order No. DA9319299

An experimental study of the nonlinear spectral development associated with the transition of an initially laminar planar jet shear layer is presented. The local shear layer spectral dynamics are modeled as a nonlinear system containing both linear and two quadratically nonlinear system elements. The experimental technique motivated by the related governing equation for the flow is based upon the 'wave coupling equation' which results from a temporal Fourier transform of the incompressible Navier-Stokes equation. A novel digital signal processing technique is applied which allows the local spectral dynamics to be estimated directly from time-series velocity fluctuations. From the linear coupling coefficient, the local spectral growth rate and dispersion relation can be estimated. Of particular interest is the associated wave coupling coefficients which provides a measure of the efficiency of local nonlinear wave-wave interactions. These show that the jet shear layer exhibits a strong preference for difference mode interactions. Particular emphasis is placed upon discerning the mechanism which gives rise to subharmonic resonance with the fundamental instability. Results show that the amplification of the subharmonic instability is largely due to a 'parametric resonance' with the fundamental rather than by direct fundamental-subharmonic interaction. Based upon the result of the dual-input/single-output nonlinear system model, it is surprising to note that u-v nonlinear interaction (i.e., f(sub e) at u + f(sub e) at v yields 2f(sub e) at u) plays a primary role in the amplification of the harmonic 2f(sub e) at u while the contribution from self-interaction of the fundamental f(sub e) (i.e., f(sub e) at u + f(sub e) at u yields 2f(sub e) at u) relatively small in the jet shear layer transition. Dissert. Abstr.

LOCAL TWO-PHASE FLOW SIMULATIONS INCLUDING INTERFACE TRACKING WITH MASS TRANSFER Ph.D. Thesis
Samuel Williamson Jo Welch 1993 180 p
Avail: Univ. Microfilms Order No. DA9320490

The purpose of this work is to develop a code to perform local simulations of fundamental two-phase fluid flows in two dimensions. We consider flows in which there is mass transfer across a phase interface separating the vapor and liquid phases. Calculation of the flow field near the interface requires that we track the location of the interface as part of the solution procedure. This work is an attempt to provide a tool to be used in understanding basic flow phenomenon near interfaces heretofore not considered in engineering two-phase flow calculations. Current practice in two-phase flow simulations is to use volume averaged equations which require engineering correlations for closure. This approach does not attempt to resolve the physics near phase interfaces. The physical phenomena near interfaces is instead approximated in subgrid models similar to the approach used in turbulence modeling. The liquid and vapor phases are considered as viscous, conducting, compressible fluids with different state equations. The interface is modeled as lines embedded in the two dimensional region. The interface is considered to have significant surface tension along with significant surface energy and entropy. The interface is nonmaterial due to the mass transfer across it. The numerical method is a finite volume method on a collocated moving mesh. The mesh motion is neither Lagrangian nor Eulerian, but rather is specified by the motion of the nonmaterial phase interface. The basic philosophy in designing the numerical method was to create a simple first order scheme allowing us to concentrate on the problems associated with the interface and the mesh motion. The basic capabilities of the scheme are illustrated in simulations both with and without mass transfer. The simulations without mass transfer are chosen to test the code against known results. The simulations with mass transfer are fundamental local simulations in two-phase flow chosen because of the simple physical insight contained within them. Dissert. Abstr.

GENERALIZED EULERIAN-LAGRANGIAN FORMULATIONS IN FREE AND MOVING BOUNDARY PROBLEMS: PROCESSING OF VISCOELASTIC POLYMERS AND FIBER SUSPENSIONS Ph.D. Thesis
Alauddin Ahmed 1993 205 p
Avail: Univ. Microfilms Order No. DA9320564

The thrust of this dissertation is to develop methods of analysis of processes associated with the manufacturing of fiber reinforced composites. The manufacturing processes are characterized by flows in complex geometries with apriori unknown free and moving boundaries. In addition, the materials are characterized by constitutive relations ranging from simple differential to complex integro-differential models. Improved and efficient mathematical formulations and numerical techniques are, therefore, required to successfully solve these complicated flow problems. The generalized Eulerian-Lagrangian (GEL) formulation provides an excellent opportunity to address some of the difficulties associated with these problems. The processes are modeled using the complete unsteady form of the conservation equations and solved using a classical mixed Galerkin finite element method coupled with Newton-Raphson iterations. In the analysis of injection and compression molding of viscoelastic polymers, the White-Metzner model is used to describe the stress state and the components of the stress tensor are treated as independent variables. The unsteady flow of dilute fiber suspensions is analyzed using the transversely isotropic fluid approach. The orientation state of the fibers is expressed in terms of orientation tensors and the development of fiber orientation is described by means of evolution equations. The model is completed using a second order quadratic closure approximation. The resulting flow field and implied fiber orientation agree well with the available experimental results. In the analysis of the semiconcentrated fiber suspensions, the Dinh-Armstrong integral constitutive equation is used to describe the stress and fiber orientation state. The Currie approximation is used to express the integral equation in the form of algebraic equations involving the finite deformation tensors and their invariants. These tensors are expressed in terms of the flow kinematics through a semi-implicit finite difference scheme. The accuracy of the scheme is tested on a radially diverging source flow for which the analytical solutions are obtained. The method is used in the analysis of the filling of simple injection and compression molding cavities. The flow pattern and fiber orientation agree well with the available experimental results. Dissert. Abstr.

TRANSITION TO TURBULENCE IN CONFINED COMPRESSIBLE MIXING LAYERS Ph.D. Thesis
Ho-Shuenn Huang 1992 270 p
Avail: Univ. Microfilms Order No. DA9312686

Four different numerical schemes have been tested at a subsonic convective Mach number: a spectral method, a fourth-order compact scheme, a second-order TVD/MacCormack scheme, and a TVD method. A spectral numerical method is chosen as the numerical scheme to investigate mixing layers from subsonic to supersonic convective Mach numbers. Two types of initial conditions are involved. One comes from linear stability theory; the other uses finite, broadband white noise. Results of the simulations reveal that, in a mixing layer subjected to perturbations consisting of finite, broadband white noise, the perturbations will grow in the linear regime close to the predictions of normal-mode analysis. There are modes which grow algebraically at early times. The three dimensional effects developing from oblique Kelvin-Helmholtz (K-H) instabilities and streamwise minus modes are also important when the flow becomes strongly nonlinear. Mushroom structures form owing to the effects of such three dimensional instabilities. Mixing is governed by the evolution of both two and three dimensional K-H instabilities. If the Reynolds number is low enough viscous shocks are likely to form during the nonlinear development. Complicated mushroom structures are observed in the evolution of the mixing interface as the mixing layers become strongly nonlinear; such succeeding development of entangling mushroom structures is believed to be the key mechanism leading to the transition to turbulence. Mixing is dominated by the three dimensional evolution of the mixing layers, e.g., oblique K-H instabilities and streamwise minus modes. For the supersonic convective Mach number, the mixing layers are dominated in the transitional regime by the development of two dimensional, confined supersonic modes. Viscous shocks interact with other unstable modes and develop in a three dimensional manner. Mixing is governed mainly by the development of two dimensional confined supersonic instabilities. The energy transfer among various modes is examined in two ways for subsonic, transonic, and supersonic convective Mach numbers. In one method a mode of potential importance is suppressed, and the resulting effect on other modes of interest is examined. A second method employs Fourier decomposition and examines the modal energy transfer rate due to triad interaction. Dissert. Abstr.

Using gas-liquid two phase flow theory, a modified mathematical model based on the computational fluid dynamics method SIMPLE (Semi Implicit Method for Pressure Linked Equations) is introduced to investigate implosion phenomena in high pressure chambers. For a characteristic physical model, the numerical results are obtained and analyzed, without referring to experimental data. Extensive calculations to predict the highest pressure on the chamber wall are performed under varying conditions such as the implosion pressure, the dimensions of the test models, and the height of the upper air layer. The efficiency of different highest pressure reduction methods is analyzed. The results of these simulations and predictions are shown in a series of plots. ESA

HOLOGRAPHIC INTERFEROMETRY: A USER'S GUIDE
D. Griggs Oct. 1993 31 p
(Contract DE-AC04-94AL-85000)
(DE94-003136; SAND-92-2909) Avail: CASI HC A03/MF A01

This manual describes the procedures and components necessary to produce a holographic interferogram of a flow field in the Sandia National Laboratories hypersonic wind tunnel. In contrast to classical interferometry, holographic interferometry records the amplitude and phase distribution of a lightwave passing through the flow field at some instant of time. This information can then be reconstructed outside the wind tunnel for visual analysis and digital processing. This yields precise characterizations of aerodynamic phenomena. The reconstruction and subsequent hologram image storage process is discussed, with particular attention paid to the digital image processor and the data reduction technique. DOE

HEAT FLUX INSTRUMENTATION FOR HYFLITE THERMAL PROTECTION SYSTEM Final Report, 13 Aug. 1993 - 13 Jan. 1994
T. E. Diller 1994 29 p
(Grant NAG1-1538)
(NASA-CR-195731; NAS 1.26:195731; NLPN-93-428) Avail: CASI HC A03/MF A01

Using Thermal Protection Tile core samples supplied by NASA, the surface characteristics of the FRCI, TUFI, and RCG coatings were evaluated. Based on these results, appropriate methods of surface preparation were determined and tested for the required sputtering processes. Sample sensors were fabricated on the RCG coating and adhesion was acceptable. Based on these encouraging results, complete Heat Flux Microsensors were fabricated on the RCG coating. The issue of lead attachment was addressed with the annnealing and welding methods developed at NASA Lewis. Parallel gap welding appears to be the best method of lead attachment with prior heat treatment of the sputtered pads. Sample Heat Flux Microsensors were submitted for testing in the NASA Ames arc jet facility. Details of the project are contained in two attached reports. One additional item of interest is contained in the attached AIAA paper, which gives details of the transient response of a Heat Flux Microsensors in a shock tube facility at Virginia Tech. The response of the heat flux sensor was measured to be faster than 10 micro-s. Author (revised)

DEVELOPMENT AND APPLICATION OF A THERMISTOR CURRENT METER Final Report
Carl M. Way, Albert J. Burky, and Christine A. Miller-Way Jan. 1994 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275816; WES/TR-EL-94-1) Avail: CASI HC A03

This report provides details for the construction of a hot-bead thermistor current meter which is capable of measuring water velocities on a millimeter spatial scale and for the construction of a compact and accurate calibration system. Hot-bead thermistor current meters can be built with response times of 200 ms capable of measuring velocities between 0.1 and 80 cm/s. The construction of a sturdy probe for application in lotic systems such as high gradient Hawaiian streams was achieved by the use of heavy-duty acrylic tubing, small stainless steel gas-chromatography tubing, and flexible Tygon spaghetti tubing. An acrylic handle anchors the electrical cable at one end and the thermistors at the other. The following criteria were central to the development of the calibration system: (1) accurate calibration; (2) compact unit for storage and use in limited laboratory space; (3) leak-proof system; (4) inexpensive design requirement for readily available materials; and (5) construction requirements for the use of hand tools. The thermistor current meter has been used to measure velocities in the water column and around various substrate features in riverine habitats. More detailed spatial velocity measurements were made in streams by dividing a habitat into small grid cells. With fine spatial scales (e.g., grid sizes of 200 to 300 sq cm or less) and repetitive sampling under varying water flow conditions, insights into relationships between various spatial and temporal characteristics of microhabitat velocities were made. The current meter has been used to determine ambient velocity profiles around a variety of benthic streams. DTIC

CRYOGENIC PROBE STATION FOR USE IN AUTOMATED MICROWAVE AND NOISE FIGURE MEASUREMENTS
Susan R. Taub, Samuel A. Alterovitz, Paul G. Young, Ben T. Ebihara, and Robert R. Romanofsky Mar. 1994 11 p Proposed for presentation at the Automated RF Techniques Group Meeting, San Diego, CA, 27 May 1994; sponsored by IEEE, MTIS and ARFTG
(RTOP 235-01-0B)
(NASA-TM-106560; E-8726; NAS 1.15:106560) Avail: CASI HC A03/MF A01

A cryogenic measurement system capable of performing on-wafer RF testing of semiconductor devices and circuits has been developed. This 'CryoProbe Station' can wafer-probe devices and circuits at cryogenic temperatures, thus eliminating the need for wire bonds. The system operates under vacuum created by a sorption pump. It uses an open cycle cooling system that can be cooled with either liquid nitrogen or liquid helium. Presently, it can reach temperatures, as low as 80 K and 37 K for each of the coolants, respectively. The temperature can be raised using a heater and it is stabilized to within 0.2 K by use of a temperature controller. The CryoProbe Station features a 1 by 2 inch stage that can hold large circuits and calibration standards simultaneously. The system is used with a Hewlett Packard 8510C Automatic Network Analyzer (ANA) to obtain S-parameter data over the frequency range 0.045-26.5 GHz. S-parameter data on HEMT (high electron mobility transistors) devices has been obtained with this station. With the use of DEEMBED software from NIST, detailed transmission line studies have been performed. Although the CryoProbe Station is designed for frequencies up to 26.5 GHz, useful transmission line data has been obtained for frequencies as high as 40 GHz. The CryoProbe station has also been used with the ATN noise figure measurement system to perform automatic, temperature dependent noise figure measurements. Author

DOUBLE-CRYSTAL ANALYSER SYSTEM FOR THE PRISMA SPECTROMETER: TEST OF A PROTOTYPE
C. Petrillo, F. Sacchetti, M. Hagen, and U. Steigenberger Nov. 1993 44 p Prepared in cooperation with Istituto Nazionale di Fisica Nucleare, Frascati, Italy and Keele Univ., England
(PB94-138245; RAL-93-091) Avail: Issuing Activity (National Technical Information Service (NTIS))

A prototype of a double-analyzer system has been tested at the ISIS pulsed neutron source in order to determine the performance of such an analyzing device in the low energy transfer region. The performance of

such a system has been found satisfactory in terms of reflectivity and energy resolution as well as alignment procedures. Based on our test results, we propose the construction of a second arm for the PRISMA spectrometer at ISIS. This new arm would enable us to perform measurements with much improved energy resolution and to extend the wavevector transfer range to much smaller values, thus improving the instrument performance significantly for magnetic scattering experiments. The new, modular approach of the upgrade will also strengthen the flexibility of the instrument and open up the opportunity for further instrumental developments, for example the introduction of a polarization option. ABSOLUTE CALIBRATION TECHNIQUE FOR BROADBAND ULTRASONIC TRANSDUCERS Patent Application

William T. Yost, inventor (to NASA) and John H. Cantrell, inventor (to NASA) 31 Aug. 1993 15 p

(NASA-Case-LAR-14672-1; NAS 1.71:LAR-14672-1;

US-Patent-Appl-SN-117511) Avail: CASI HC A03/MF A01

Calibrating an ultrasonic transducer can be performed with a reduced number of calculations and testing. A wide-band pulser is connected to an ultrasonic transducer under test to generate ultrasonic waves in a liquid. A single frequency is transmitted to the electrostatic acoustic transducer (ESAT) and the voltage change produced is monitored. Then a broadband ultrasonic pulse is generated by the ultrasonic transducer and received by the ESAT. The output of the ESAT is amplified and input to a digitized oscilloscope for fast Fourier transform. The resulting plot is normalized with the monitored signal from the single frequency pulse. The plot is then corrected for characteristics of the membrane and diffraction effects. The transfer function of the final plot is determined. The transfer function gives the final sensitivity of the ultrasonic transducer as a function of frequency. The advantage of the system is the speed of calibrating the transducer by a reduced number of measurements and removal of the membrane and diffraction effects.

SUSPENSION SYSTEM FOR GIMBAL SUPPORTED SCANNING PAYLOADS Patent Application

Michael E. Polites, inventor (to NASA) 15 Sep. 1993 22 p

(NASA-Case-MFS-28817-1; NAS 1.71:MFS-28817-1;

US-Patent-Appl-SN-123629) Avail: CASI HC A03/MF A01

Gimballed scanning devices or instruments are the subject of this invention. Scanning is an important aspect of space science. To achieve a scan pattern some means must be provided which impart to the payload an oscillatory motion. Various forms of machines have been employed for controllably conferring on scanning instruments predetermined scan patterns. They include control moment gyroscopes, reaction wheels, torque motors, reaction control systems, and the like. But rotating unbalanced mass (RUM) devices are a new and efficient way to generate scans in gimballed payloads. RUM devices are superior to previous scanning apparatus, but they require power consuming and frequently complex auxiliary control systems to position and reposition the particular scan pattern relative to a target or a number of targets. Herein the control system is simplified. The most frequently employed method for achieving the various scan patterns is to gimbal the scanning device. Gimbals are suspended in such a way that they can be activated to generate the scan pattern. The suspension means described is for payloads supported in gimbals wherein the payload rotation is restricted by a flex pivot so that the payload oscillates, thereby moving in a scan pattern.

OPTICAL FLAMEOUT DETECTOR Patent Application

Stephen E. Borg, inventor (to NASA), James W. West, inventor (to NASA), Robert M. Lawrence, inventor (to NASA), Samuel E. Harper, Jr., inventor (to NASA), and David W. Alderfer, inventor (to NASA) 19 Oct. 1993 12 p

(NASA-Case-LAR-14997-1; NAS 1.71:LAR-14997-1;

US-Patent-Appl-SN-141294) Avail: CASI HC A03/MF A01

A device has been developed which monitors the presence of a flame within a combustion chamber. The optical flameout detection system responds to gross changes in combustor light intensity, which is monitored in two spectral bands. A photomultiplier tube makes optical measurements in the ultraviolet portion of the spectrum, and a silicon photodiode covers the visible region. The detectors, located outside the combustion chamber, receive the light energy radiated from the combustion process through fiber optic probes designed to operate in a high pressure environment. The optical fibers are aimed diagonally through the center of the injector at the combustion chamber wall downstream of the injector. The probes observe events occurring within a narrow conical-shaped field of view so that the system can quickly detect longitudinal movement of the flame front away from the injector. If a change in intensity of the flame is detected, the fuel supply to the combustion chamber is shut off, limiting the amount of unburned fuel in the combustion chamber which could reignite.

DIGITAL CAMERA WITH APPARATUS FOR AUTHENTICATION OF IMAGES PRODUCED FROM AN IMAGE FILE Patent Application

Gary L. Friedman, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 24 Nov. 1993 22 p

(Contract NAS7-918)

(NASA-Case-NPO-19108-1-CU; NAS 1.71:NPO-19108-1-CU;

US-Patent-Appl-SN-159980) Avail: CASI HC A03/MF A01

A digital camera equipped with a processor for authentication of images produced from an image file taken by the digital camera is provided. The digital camera processor has embedded therein a private key unique to it, and the camera housing has a public key that is so uniquely based upon the private key that digital data encrypted with the private key by the processor may be decrypted using the public key. The digital camera processor comprises means for calculating a hash of the image file using a predetermined algorithm, and second means for encrypting the image hash with the private key, thereby producing a digital signature. The image file and the digital signature are stored in suitable recording means so they will be available together. Apparatus for authenticating at any time the image file as being free of any alteration uses the public key for decrypting the digital signature, thereby deriving a secure image hash identical to the image hash produced by the digital camera and used to produce the digital signature. The apparatus calculates from the image file an image hash using the same algorithm as before. By comparing this last image hash with the secure image hash, authenticity of the image file is determined if they match, since even one bit change in the image hash will cause the image hash to be totally different from the secure hash.

CONTROLLED THERMAL EXPANSION PRINTED WIRING BOARDS BASED ON LIQUID CRYSTAL POLYMER DIELECTRICS

Thomas E. Knoll, Kent Blizard, K. Jayaraj, and Leslie S. Rubin Apr. 1994

11 p
(Contract NAS5-31996)
(NASA-CR-189338; NAS 1.26:189338) Avail: CASI HC A03/MF A01

Dielectric materials based on innovative Liquid Crystal Polymers (LCP's) have been used to fabricate surface mount printed wiring boards (PWB's) with a coefficient of thermal expansion matched to leadless ceramic chip carriers. Proprietary and patented polymer processing technology has resulted in self reinforcing material with balanced in-plane mechanical properties. In addition, LCP's possess excellent electrical properties, including a low dielectric constant (less than 2.9) and very low moisture absorption (less than 0.02%). LCP-based multilayer boards processed with conventional drilling and plating processes show improved performance over other materials because they eliminate the surface flatness problems of glass or aramid reinforcements. Laser drilling of blind vias in the LCP dielectric provides a very high density for use in direct chip attach and area array packages. The material is ideally suited for MCM-L and PCMCIA applications fabricated with very thin dielectric layers of the liquid crystal polymer.

THE USE OF DIGITAL STEREO PHOTOGRAMMETRIC METHODS IN HISTORICAL PHOTO ANALYSIS
Glenn Frano, Daniel Edwards, Mitchell Pierson, Maurits Roos, and Michael Barwick Jan. 1994 11 p
(AD-A275287) Avail: CASI HC A02/MF A01

A historical, temporal photointerpretation method is presented for combining the use of a current digital stereo photogrammetric system with manual photointerpretation techniques. The U.S. Army Topographic Engineering Center was tasked to provide products showing the current three-dimensional position of certain features present on a 1918 photomosaic. This mosaic is over a former chemical munitions test area in Washington, D.C.. In order to provide this data, aerial photography from 1918, 1927, 1991 and 1993 was used in the process. This paper will discuss the front end research and collection of textual and photographic data, the manual photo interpretation process, the photogrammetric process and its accuracies, the problems encountered, the digital mapping process and the final products. (NASA-Case-LAR-14029-1; NAS 1.71:LAR-14029-1;
US-Patent-Appl-SN-138046) Avail: CASI HC A03/MF A01

A method for providing a perfectly flat top with a sharp edge on a dynamic pressure sensor using a cup-shaped stretched membrane as a sensing element is described. First, metal is deposited on the membrane and surrounding areas. Next, the side wall of the pressure sensor with the deposited metal is machined to a predetermined size. Finally, deposited metal is removed from the top of the membrane in small steps, by machining or lapping while the pressure sensor is mounted in a jig or the wall of a test object, until the true top surface of the membrane appears. A thin indicator layer having a color contrasting with the color of the membrane may be applied to the top of the membrane before metal is deposited to facilitate the determination of when to stop metal removal from the top surface of the membrane. AN ALTERNATE METHOD FOR ACHIEVING TEMPERATURE CONTROL IN THE -160 TO +90 C RANGE Patent Application
Kenneth R. Johnson, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 4 Nov. 1993 34 p
(Contract NAS7-918)
(NASA-Case-NPO-18995-1-CU; NAS 1.71:NPO-18995-1-CU;
US-Patent-Appl-SN-152631) Avail: CASI HC A03/MF A01

A single-pass method for accurate and precise temperature control in the -160 to +90 C range is discussed. The method exhibited minimal set-point overshoot during temperature transitions. Control to +/-2 C with transitions between set-points of 7 C per minute were achieved. The method uses commercially available temperature controllers and a gaseous nitrogen/liquid nitrogen mixer to dampen the amplitude of cold temperature spikes caused by liquid nitrogen pulsing. NASA

A device for testing fasteners such as nuts and bolts is described which consists of a fixed base plate having a number of threaded and unthreaded holes of varying size for receiving the fasteners to be tested, a torque marking paper taped on top the fixed base plate for marking torque-angle indicia, a torque wrench for applying torque to the fasteners being tested, and an indicator for showing the torque applied to the fastener. These elements provide a low cost, nondestructive device for verifying the strength of bolts and nuts.

THREE-AXIS FIBER OPTIC VECTOR MAGNETOMETER Patent
Kee P. Koo, inventor (to Navy), George H. Sigel, Jr., inventor (to Navy), and Frank Bucholtz, inventor (to Navy) 7 Sep. 1993 7 p Filed 30 Sep. 1991
(AD-D016016; US-Patent-5,243,403; US-Patent-Appl-SN-767955) Avail: US Patent and Trademark Office

This patent discloses a three-axis fiber optic vector magnetometer which is provided for measuring both the direction and magnitude of a DC or low frequency magnetic field. The magnetometer includes an optical interferometer system including a sensing fiber arm disposed with three respective sensing portions perpendicular to one another and attached to a unidirectional sensor material. The interferometer system also includes a reference fiber arm and a laser light source for generating and introducing a laser light into both of the arms. Respective biasing devices generate a reference AC magnetic bias and a respective reference frequency in the three sensing portions. A detecting device detects a reference light signal from the reference fiber arm and the magnetically altered sensing light signal from the sensing fiber arm and forms an interferometer output signal. Respective separating devices then separate the respective magnetically induced interferometer signals at respective ones of the frequencies and produce a respective output signal indicative thereof. Int-Patent-Class-B25J-11/00) Avail: US Patent and Trademark Office

A Six-Degree-of-Freedom Parallel-Manipulator having three inextensible limbs for manipulating a platform is described. The three inextensible limbs are attached via universal joints to the platform at non-collinear points. Each of the inextensible limbs is also attached via universal joints to a two-degree-of-freedom parallel driver such as a five-bar linkage, a pantograph, or a bidirectional linear stepper motor. The drivers move the lower ends of the limbs parallel to a fixed base and thereby provide manipulation of the platform. The actuators are mounted on the fixed base without using any power transmission devices such as gears or belts.

STEREO IMAGING BASED PARTICLE VELOCIMETER Final Technical Report
Celal Batur 16 Apr. 1994 22 p
(Contract NCC3-231)
(NASA-CR-195800; NAS 1.26:195800) Avail: CASI HC A03/MF A01

Three dimensional coordinates of an object are determined from it's two dimensional images for a class of points on the object. Two dimensional images are first filtered by a Laplacian of Gaussian (LOG) filter in order to detect a set of feature points on the object. The feature points on the left and the right images are then matched using a Hopfield type optimization network. The performance index of the Hopfield network contains both local and global properties of the images. Parallel computing in stereo matching can be achieved by the proposed methodology. Author

AN ACTIVELY COOLED FLOATING ELEMENT SKIN FRICTION BALANCE FOR DIRECT MEASUREMENT IN HIGH ENTHALPY SUPERSONIC FLOWS Ph.D. Thesis
Kenneth Michael Chadwick 1992 178 p
Avail: Univ. Microfilms Order No. DA9312871

An investigation was conducted to design instruments to directly measure skin friction along the chamber walls of supersonic combustor models. Measurements were made in a combustor at the General Applied Science Laboratory (GASL) and in the Direct Connect Arcjet Facility (DCAF) supersonic combustor at the NASA AMES Research Center. Flow conditions in the high enthalpy combustor models ranged from total pressures of 275-800 psia (1900-5550 kPa) and total temperatures from 5800-8400 R (3222-4667 K). This gives enthalpies in the range of 1700-3300 BTU/lb(sub m) (3950-7660 KJ/kg) and simulated flight Mach number from 9 to 13. A direct force measurement device was used to measure the small tangential shear force resulting from the flow passing over a non-intrusive floating element. The floating head is mounted to a stiff cantilever beam arrangement with deflection due to the shear force on the order of 0.0005 in (0.0125 mm). This small deflection allows the balance to be a non-nulling type. Several measurements were conducted in cold supersonic flows to verify the concept and establish accuracy and repeatability. This balance design includes actively controlled cooling of the floating sensor head temperature through an internal cooling system to eliminate non-uniform temperature effects between the head and the surrounding chamber wall. This enabled the device to be suitable for shear force measurement in very hot flows. The key to this device is the use of a quartz tube cantilever with strain gages bonded at orthogonal positions directly on the surface at the base. A symmetric fluid flow was developed inside the quartz tube to provide cooling to the backside of the floating head. Bench tests showed that this did not influence the force measurement. Numerical heat transfer calculations were conducted for design feasibility and analysis, and to determine the effectiveness of the active cooling of the floating head. Analysis of the measurement uncertainty in cold supersonic flow tests show that uncertainty under 8 percent is achievable, but variations in the balance cooling during a particular test raised uncertainty up to 20 percent in these very hot flows during the early tests. Improvements to the strain gages and balance cooling reduced uncertainty for the later tests to under 15 percent.

DEFORMED ELLIPSOIDAL DIFFRACTION GRATING BLANK Final Report
Alan E. DeCew, Jr. Mar. 1994 113 p
(Contract NAS5-31790)
(NASA-CR-189334; NAS 1.26:189334) Avail: CASI HC A06/MF A02

The Deformed Ellipsoidal Grating Blank (DEGB) is the primary component in an ultraviolet spectrometer. Since one of the major concerns for these instruments is throughput, significant efforts are made to reduce the number of components and subsequently reflections. Each reflection results in losses through absorption and scattering. It is these two sources of photon loss that dictated the requirements for the DEGB. The first goal is to shape the DEGB in such a way that the energy at the entrance slit is focused as well as possible on the exit slit. The second goal is to produce a surface smooth enough to minimize the photon loss due to scattering. The program was accomplished in three phases. The first phase was the fabrication planning. The second phase was the actual fabrication and initial testing. The last phase was the final testing of the completed DEGB. Author

A SOUNDING ROCKET PROGRAM IN EXTREME AND FAR ULTRAVIOLET INTERFEROMETRY Final Technical Report
S. Chakrabarti 29 Apr. 1994 2 p
(Grant NAG5-675)
(NASA-CR-195114; NAS 1.26:195114) Avail: CASI HC A01/MF A01

A self-compensating, all reflection interferometric (SCARI) spectrometer was developed that can provide high resolution measurements of spectral features at any wavelength. Several mechanical components were developed that aid the instrument's performance at the short wavelength range. Examples include an optical bench and modular removable precision mechanisms for alignment. Upon alignment and lock down of the interferometer with the latter, the device is removed to minimize weight. A ray-trace code was developed to simulate the instrument's performance. Interference patterns were obtained at the shortest wavelength: the hydrogen Lyman alpha (1216 A). A laboratory instrument was developed that will be flown aboard a Black Brant sounding rocket to study the very local interstellar medium. Derived from text

A NON-CONTACTING VERTICAL ALIGNMENT SYSTEM FOR MASS PROPERTIES MEASURING INSTRUMENTS
G. H. James, III, J. E. Suazo, and R. C. Varga Nov. 1993 79 p
(Contract DE-AC04-94AL-85000)
(DE94-004680; SAND-93-1425) Avail: CASI HC A05/MF A01

A non-contact system for the alignment of objects on mass properties measuring instruments is described. Test parts can be aligned to within the capabilities of the user and the fixture to make the adjustments. The current implementation can align objects to less than .001 inches at two points with final requested adjustments of a few ten-thousands of an inch. The non-contact capability allows the alignment of objects which are too compliant or fragile for traditional contacting measurement methods. Also, this system allows the definition of a reference axis for objects which are not perfectly symmetric. The reference axis is defined at the top of the object by an appropriate marker and defined at the bottom by a best fit circle through the surface at a specified height. A general description of the hardware, procedures, and results are presented for the non-user. Appendices which contain a complete description of the software, usage, and mathematical implementation are provided for the reader who is interested in using or further developing the system. DOE

PHOTOELECTRON DIFFRACTION AND HOLOGRAPHY: SOME NEW DIRECTIONS
C. S. Fadley (California Univ., Davis.) Aug. 1993 26 p Presented at the 4th International Conference on the Structure of Surfaces, Shanghai, China, 16-19 Aug. 1993
(Contract DE-AC03-76SF-00098)
(DE94-006297; LBL-35051; CONF-9308154-3) Avail: CASI HC A03/MF A01

Photoelectron diffraction has by now become a versatile and powerful technique for studying surface structures, with special capabilities for resolving chemical and magnetic states of atoms and deriving direct structural information from both forward scattering along bond directions and back-scattering path length differences. Further fitting experiment to theory can lead to structural accuracies in the +/- 0.03 Angstrom range. Holographic inversions of such diffraction data also show considerable promise for deriving local three-dimensional structures around a given emitter with accuracies of +/- 0.2-0.3 Angstrom. Resolving the photoelectron spin in some way and using circularly polarized radiation for excitation provide added dimensions for the study of magnetic systems and chiral experimental geometries. Synchrotron radiation with the highest brightness and energy resolution, as well as variable polarization, is crucial to the full exploitation of these techniques. DOE

MICROWAVE MICHELSON INTERFEROMETER SYSTEM REPORT OF FIRST USE ON A RAILGUN, GREEN FARM, SAN DIEGO, CA

R. S. Hawke, D. Greenwood, J. Morrison, and F. Schildmeyer 20 Oct. 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-005294; UCRL-ID-115694) Avail: CASI HC A02

This report summarizes the successful first attempt to use a Michelson microwave interferometer to measure the position of a projectile throughout its acceleration by a railgun. The test was performed at the DNA Green Farm facility operated by Maxwell Labs Inc. The test was performed using the ARDEC-ACB gun to accelerate a 1.1 kg polycarbonate projectile to about 2.5 km/s. The projectile had an initial injection velocity of about 490 m/s. DOE

MESO-OPTICAL FOURIER TRANSFORM MICROSCOPE WITH DOUBLE FOCUSING

Yu. A. Batusov, L. M. Soroko, and V. V. Tereshchenko 1992 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-607851; JINR-E-13-92-179) Avail: CASI HC A03 (US Sales Only)

The meso-optical Fourier transform microscope (MFTM) with double focusing for particle tracks of low ionization level in the nuclear emulsion is described. It is shown experimentally that this device enables one to get high concentration of information about the position of the particle track in the nuclear emulsion and thus to increase the signal-to-noise ratio. It is shown that spreading of the meso-optical image of the particle track in the sagittal section of the MFTM can be eliminated completely in the frame of the diffraction limit. The number of the additional degrees of freedom in this new MFTM system along depth coordinate is equal to 20 in comparison to single degree of freedom in the Fourier transform microscope of the direct observation. DOE

AMPOULE FAILURE SENSOR TIME RESPONSE TESTING: EXPERIMENT 1

M. L. Johnson and D. A. Watring Apr. 1994 15 p
(NASA-TM-108449; NAS 1.15:108449) Avail: CASI HC A03/MF A01

The response time of an ampoule failure sensor exposed to a liquid or vapor gallium-arsenide (GaAs) is investigated. The experimental configuration represents the sample/ampoule cartridge assembly used in NASA's Crystal Growth Furnace (CGF). The sensor is a chemical fuse made from a metal with which the semiconductor material reacts more rapidly than it does with the containing cartridge. For the III-IV compound of GaAs, a platinum metal was chosen based on the reaction of platinum and arsenic at elevated temperatures which forms a low melting eutectic. Ampoule failure is indicated by a step change in resistance of the failure sensor on the order of megohms. The sensors will increase the safety of crystal growth experiments by providing an indication that an ampoule has failed. Experimental results indicate that the response times (after a known ampoule failure) for the 0.003 and 0.010 inch ampoule failure sensors are 2.4 and 3.6 minutes, respectively. This ampoule failure sensor will be utilized in the CGF during the second United States Microgravity Laboratory Mission (USML-2) and is the subject of a NASA patent application.

CALIBRATION OF CHARGE COUPLED DEVICE DIGITAL CAMERAS M.S. Thesis [CALIBRAGE DE CAMERAS NUMERIQUES CCD]

Martin Brindamour Oct. 1993 115 p In FRENCH
(ISBN-0-315-85539-8; CTN-94-61147) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

The arrival of charge coupled device (CCD) cameras has revolutionized short-range photogrammetry. A prototype system of measurement and representation of small objects (METRICAN), based on use of CCD cameras, was developed at Laval University. Since the cameras used are non-metrical cameras, calibration of their internal geometry must be carried out before taking measurements. A study was conducted to verify whether adding polynomials modelling the distortions to the mathematical model of calibration could improve the metrical precision of the system. It is shown that it is important to consider the radial distortion in calibration. The tangential distortion can be ignored due to its small contribution. The effects of adding an infrared filter to faces parallel to the different distortion components were also examined. The presence of the infrared filter, which facilitates the automatic reconnaissance of the measuring points, does not significantly modify the value of the interior orientation parameters. CISTI

TIME-RESOLVED HOLOGRAPHY FOR THE MICROSCOPIC STUDY OF CRACK-TIP MOTION IN DYNAMIC FRACTURE Ph.D. Thesis

John Scott Steckenrider 1993 188 p
Avail: Univ. Microfilms Order No. DA9313436

A novel laser system has been designed and developed for the time-resolved holographic analysis of dynamic crack propagation with a frame-to-frame resolution of from 28.3 to 161.6 ns. Average velocities of approximately 1300 m/s were measured in macroscopic (1.2 mm thick) glass specimens, and velocities of 1200 m/s were measured in microscopic (0.15 mm thick) glass specimens. Holographic analyses were conducted using both diffuse and direct laser illumination, demonstrating a broad range of applicability for this method. Normalized crack length versus time plots were generated for a series of specimens with pre-crack lengths of from 3.5 to 10.5 mm wing various pre-load levels and initiating explosive sizes. All specimens exhibited similar dynamic fracture behavior, particularly those outside of the region of shock of the initiating explosive (those of the longer pre-crack set). A best-fit to the theoretical prediction for mode I crack growth revealed a good match to the case for a specimen overloaded by 64 percent. However, no variation with applied load was evident, indicating that an immediate acceleration to a velocity of approximately 1200 m/s (near the empirically determined terminal velocity) was the more plausible fit. Since the terminal velocity was approximately the same for all specimens, this investigation also demonstrated that the terminal velocity is independent of crack-tip stresses, even for the most extreme explosive pulses. In addition, a different loading configuration was attempted in which the specimen was shielded from the explosive shock. The resulting crack growth behavior displayed a velocity well below the aforementioned terminal velocity, indicating an acceleration was present. However, owing to the lack of reproducibility in this method of loading, repeated experiments were not possible. Finally, applications of the described laser system for use in laser ultrasonics were investigated, and these results are included.

DETERMINATION OF ACCELERATION FIELD PARAMETERS WITH LINEAR ACCELEROMETERS

J. P. B. Vreeburg 29 Apr. 1992 15 p Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-125606; NLR-TP-92184-U; ETN-94-95580) Avail: CASI HC A03

The ballistometer carried on the Wet Satellite Model (WSM), whose output provides the WSM motional parameters, is described. From these data and knowledge of the ten inertial parameters of the solid part of the WSM, it is possible to determine the force and torque exerted by liquid carried in an onboard tank. These data are needed for the verification of capillary liquid slosh models. The linear and angular motions of a rigid body induce an acceleration field that is described in a coordinate system fixed to the body. The response of a linear accelerometer to this field depends on the magnitude and direction of the motional parameters, and on this configuration, that is, its location and the direction of the sensitive axis. Combination of the signals from an arrangement of accelerometers allows reconstitution of the linear and angular acceleration, and the angular rate vectors of the body. Formulas for the analysis of arbitrary arrangements of three, six and nine accelerometers are given. Substitution of the Newton and the Euler equations in the formula for the force field expresses the acceleration as a function of force and torque and the ten inertial parameters of the body. Possible applications are indicated. ESA

THE USE OF THERMISTORS IN THE NPL ELECTRON-BEAM CALORIMETER

M. R. McEwen, D. T. Burns, and A. J. Williams Mar. 1993 18 p
(ISSN 0955-9655)
(PB94-139334; NPL-RSA(Ext)-41; ETN-94-95849) Copyright Avail: Issuing Activity (National Physical Lab., Teddington, Middlesex TW11 0LW, England)

The system developed for calibrating thermistors, which have been employed in the primary standard electron beam graphite calorimeter for several years, and the results of investigations into self-heating and dose response are described. The overall uncertainty in measuring temperature rises is estimated to be +/- 0.1 percent at the 95 percent confidence level. The self-heating of the thermistor type used in the calorimeter was determined to be constant over the temperature range 14 to 29 C. The same thermistor type showed no change in response within the uncertainties to an accumulated dose up to 3000 kGy. A second type of thermistor (to be used in a new calorimeter) showed no change in sensitivity although there was a change in absolute resistance of approximately 0.1 percent per MGy. ESA

A LOW NOISE SILICON DETECTOR PREAMPLIFIER SYSTEM FOR ROOM TEMPERATURE X RAY SPECTROSCOPY
A. Pullia 1993 8 p
(Rept-93-058; ETN-94-95820) Avail: Issuing Activity (Politecnico di Milano, Piazza Leonardo da Vinci 32, 20133 Milan, Italy)

The design and performances of a system for high resolution x-ray spectroscopy are presented. The detector is a low capacitance diode built on high resistivity silicon. The signal preamplification is made by means of an ultra-low noise charge amplifier. The system exhibits an equivalent noise charge of 61 root mean square electrons at 297K and 32 root mean square electrons at 223K. It is shown how an improvement down to 30 root mean square electrons at room temperature is expected employing an integrated transistor on the detector chip. ESA

NOISE REDUCTION TECHNIQUES FOR THE RESTORATION OF MUSICAL RECORDINGS Ph.D. Thesis [TECHNIQUES DE REDUCTION DE BRUIT POUR LA RESTAURATION D'ENREGISTREMENTS MUSICAUX]
Olivier Cappe 1993 214 p In FRENCH Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0751-1353)
(TELECOM-93-E-019; ETN-94-95983) Avail: CASI HC A10

The evaluation of short time spectral attenuation techniques using a simplified model of standard noise suppression rules and with elementary test signals is assessed. Signal distortions induced by the restoration process are evaluated analytically, and their audibility is addressed by use of classic psychoacoustics results. Phenomena observed experimentally in previous studies, such as the modification of timbre, the appearance of modulations, and the spreading of transients, are brought to light. Drawing from these results, a noise reduction technique intended for enhancing musical signals is described. In the first step, the noisy signal is analyzed by use of a medium frequency resolution short time transform. The restoration then takes place in each subband in two different ways according to the nature of the subband signal: the processing is carried out block by block when steady signal components are detected, or locally otherwise. This approach was successfully applied to several musical recordings yielding promising results. ESA

This study of laser light interactions with solid materials ranges from low temperature heating to explosive, plasma-forming reactions. Contained are works concerning laser-energy coupling: laser heating and melting monitored using a mirage effect technique, the mechanical stress-power generated during high powered laser ablation, and plasma shielding. First, a photothermal deflection (PTD) technique is presented for monitoring heat transfer during modulated laser heating of opaque solids that have not undergone phase change. Of main interest is the physical significance of the shape, magnitude, and phase for the temporal profile of the deflection signal. Considered are the effects that thermophysical properties, boundary conditions, and geometry of the target and optical probe-beam have on the deflection response. PTD is shown to monitor spatial and temporal changes in heat flux leaving the surface due to changes in laser energy coupling. The PTD technique is then extended to detect phase change at the surface of a solid target. Experimental data shows the onset of melt for indium and tin targets. The conditions for which melt can be detected by PTD is analyzed in terms of geometry, incident power and pulse length, and thermophysical properties of the target and surroundings. Next, monitoring high powered laser ablation of materials with stress-power is introduced. The motivation for considering stress-power is given, followed by a theoretical discussion of stress-power and how it is determined experimentally. Experiments are presented for the ablation of aluminum targets as a function of energy and intensity. The stress-power response is analyzed for its physical significance. Lastly, the influence of plasma shielding during high powered pulsed laser-material interactions is considered. Crater size, emission, and stress-power are measured to determine the role that the gas medium and laser pulse length have on plasma shielding. DOE

LINAC COHERENT LIGHT SOURCE (LCLS) AT 2-4 nm USING THE SLAC LINAC
J. T. Seeman, K. Bane, R. Boyce, G. Loew, P. Morton, H. D. Nuhn, J. Paterson, P. Pianetta, T. Raubenheimer, and R. Tatchyn et al Aug. 1993 10 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers (SPIE), San Diego, CA, 11-16 Jul. 1993
(Contract DE-AC03-76SF-00515)
(DE94-005235; SU-SLAC-PUB-6312; LBL-33456; CONF-930722-56) Avail: CASI HC A02/MF A01

The authors describe the possible use of the SLAC linac to drive a unique, powerful, short wavelength Linac Coherent Light Source (LCLS). Using the FEL principle, lasing is achieved in a single pass of a high peak current electron beam through a long undulator by self-amplified spontaneous-emission (SASE). The main components are a high-brightness electron RF gun with a photocathode, two electron bunch length compressors, the existing SLAC linac, beam diagnostics, and a long undulator combined with a FODO quadrupole focusing system. The RF gun, to be installed about 1 km from the end of the SLAC linac, would produce a single bunch of 6 x 10(exp 9) electrons with an invariant emittance of about 3 mm-mrad and a bunch length of about 500 (mu)m. That bunch is then accelerated to 100 MeV and compressed to a length of about 200 (mu)m. The main SLAC linac accelerates the bunch to 2 GeV were a second bunch compressor reduces the length to 30-40 (mu)m and produces a peak current of 2-3 kA. The bunch is then accelerated to 7-8 GeV and transported to a 50-70 m long undulator. Using electrons below 8 GeV, the undulator could operate at wavelengths down to 2 nm, producing about 10 GW peak power in sub-ps light pulses. At a linac repetition rate of 120 Hz, the average power is about 1 W. Linac operation at lower beam energies provides longer wavelength radiation. After the undulator, the beam is deposited in a dump. The LCLS light pulses are then distributed to multiple user stations using grazing incident mirrors. Length compression, emittance control, phase stability, FEL design criteria, and parameter tolerances are discussed. A demonstration experiment is also described which uses the SLAC linac and (possibly) the PALADIN undulator to study SASE to power saturation at wavelengths of 40-360 nm. DOE

REACTOR-PUMPED LASER EXPERIMENTAL RESULTS
G. A. Hebner and G. N. Hays 1994 11 p Presented at the International Symposium on Optoelectronic and Microwave Engineering, Los Angeles, CA, 22-28 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-005247; SAND-93-3993C; CONF-940114-1) Avail: CASI HC A03/MF A01

Reactor pumped lasers have the potential to be scaled to multi-megawatt power levels with long run times. In proposed designs, the laser will be capable of output powers of several megawatts of power for run times of several hours. Such a laser would have many diverse applications such as material processing, space debris removal and power beaming to geosynchronous satellites or the moon. However, before such systems can be designed, fundamental laser parameters such as small signal gain, saturation intensity and efficiency must be determined over a wide operational parameter space. We have recently measured fundamental laser parameters for a selection of nuclear pumped visible and near IR laser transitions in atomic neon, argon and xenon. An overview of the results of this investigation will be presented. DOE

LASER BEAM STEERING WITH SEMICONDUCTOR WAVEGUIDE Progress Report No. 3, 17 Mar. - 29 Aug. 1993
29 Aug. 1993 11 p
(AD-A275775) Avail: CASI HC A03/MF A01

The ability to rapidly and randomly steer a laser beam is critical to the success of free-space satellite-based laser radar systems for missile defense and target tracking. By applying waveguide technology, we will demonstrate multi-dimensional, all-electronic laser beam steering. Parallel arrays of electronically phase-modulated waveguide structures are being fabricated, and a metal grating was designed to spatially dissect an incident coherent planar waveform, emitted at 1059 nm by a Nd:YAG laser. The rotation of the output light-beam will occur through constructive interference effects in the far field. A two dimensional array of phase-control channels would allow scanning the beam over the entire image plane. Initial efforts in Phase 1 are being focused on fabrication and testing of a two channel, vertically situated set of buried waveguides. The implementation of a double-buried semiconductor structure with two GaAs cores and Al(x)Ga(1-x)As cladding was analyzed in detail to determine materials parameters that would allow us to demonstrate the highly novel concept of high speed, electronic laser steering of a laser beam in the vertical direction. The GaAs waveguide is being grown to contain a pn junction, while the cladding consists of Al(0.08)Ga(0.92)As, with the lower cladding doped n-type, and the upper cladding doped p-type. For a 2 micron thick waveguide, only the fundamental mode and perhaps the first harmonic can be supported, which should allow demonstration of optical interference in the far field. DTIC

(DE94-606817; NIIEFA-P-0908) Avail: CASI HC A03/MF A01 (US Sales Only)

Basic principles of setting up multiposted systems of radiation transport and focusing are discussed. Development of certain unified units, from which various systems of transport and focusing are composed, is reported and their main performances are given. Standard units, including stationary revolving mirrors, optical switches for one or two beams, universal posts, etc., permit assembly and flexible rearrangement of radiation transport systems of several powerful lasers to a number of technological posts. VISIBLE VERTICAL CAVITY SURFACE EMITTING LASERS Ph.D. Thesis
James A. Lott 1993 270 p
(AD-A275334; AFIT/CI/CIA-93-23D) Avail: CASI HC A12/MF A03

This dissertation explores the design, fabrication, and characterization of visible (620 to 690 nm) vertical cavity surface emitting lasers (VCSEL's), consisting of a strained quantum well optical cavity active region, surrounded by distributed Bragg reflectors (DBR's). The lattice-matched device structures are grown on GaAs substrates by metalorganic vapor phase epitaxy (MOVPE). The key design and fabrication issues are reviewed and contrasted with conventional near infrared (IR) VCSEL's. Design trade-offs and quantum well gain characteristics are examined by studying optically pumped structures. Device fabrication techniques are developed, and the first electrically injected visible AlGaInP VCSEL's are demonstrated. Prototype devices operate with pulsed current excitation at room temperature with a maximum output power of 3.38 mW at a lasing emission wavelength of 650 nm with threshold current densities of about 4.2 kA/sq. cm and threshold voltages of about 2.7 V. Due to cavity losses and unoptimized gain layer design, lasing is only achieved with significant gain contributions from the second (n=2) quantized quantum well state. With several design improvements, pulsed room temperature (23 deg C) lasing is achieved over the very broad range 629.6 to 691.4 nm, where the lasing emission above 650 nm is due primarily to gain contributions from the first (n=1) quantized quantum well state. (AD-A275070) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two separate experiments are described. The first was on the velocity distribution analysis of a gyrating electron beam. A retarding potential analyzer was developed which operated at 75 kV and accepted gyrating electrons with large Larmo radii. Velocity distributions were compared with simulation results. The second experiment explored the possibility of forming a large-area electron beam from polycrystalline diamond film. Diamond, a negative electron affinity material in the crystalline group of zone axes (111) direction, has been observed to emit electrons into vacuum in certain configurations, but this effort was unsuccessful in obtaining emission. HIGH-POWER CW DIODE-LASER-ARRAY-PUMPED SOLID-STATE LASERS AND EFFICIENT NONLINEAR OPTICAL FREQUENCY Final Report
Robert J. Shine and Robert L. Byer 3 Jan. 1994 9 p
(Contract DAAL03-93-G-0415)
(AD-A275394; GL-5130; ARO-32311.1-PH) Avail: CASI HC A02/MF A01

During the interim period of this bridging contract, we have continued to work on the development of high-power cw diode-laser-array-pumped solid-state lasers. Towards that end, we have built lower power lasers in order to test individual components needed for the high-power laser, specifically we have built a 1 watt ring laser and a 5 watt slab laser. The 1 watt laser was used to study the injection locking process while assembling all the necessary electronics. We have demonstrated that it is possible to injection lock a diode-pumped laser using a single piezo-mounted mirror due to the lower intrinsic laser noise compared to an arc-lamp-pumped system. This allows us to optimize the injection locking servo loop and build a more stable locking system. The 5 watt laser was used as a test bed to find a practical way to mount the slab laser while minimizing the losses that occur at the total internal reflection (TIR) points in the slab. After trying many different means of protecting the TIR surfaces, we found that a new product from DuPont, Teflon AF 1600, has all the properties needed to provide a low loss protective coating. Using this material, the laser had a cavity loss of below 2%, which allowed for efficient operation of the laser in a side-pumped design. This laser produced 5 watts of output power with a slope efficiency near 20%. DTIC

Spatial acquisition and precision beam pointing functions are critical to spaceborne laser communication systems. In the present invention, a single high bandwidth CCD detector is used to perform both spatial acquisition and tracking functions. Compared to previous lasercom hardware design, the array tracking concept offers reduced system complexity by reducing the number of optical elements in the design. Specifically, the design requires only one detector and one beam steering mechanism. It also provides the means to optically close the point-ahead control loop. The technology required for high bandwidth array tracking was examined and shown to be consistent with current state of the art. The single detector

design can lead to a significantly reduced system complexity and a lower system cost. NASA

NEAR-ULTRAVIOLET LASER PHOTOEMISSION: SCANNING MICROSCOPY, BURIED INTERFACES AND IMAGE-POTENTIAL STATES Ph.D. Thesis
Bertrand Olivier Mar Quiniou 1992 118 p
Avail: Univ. Microfilms Order No. DA9313663

This work reports the use of near-ultraviolet laser radiation, through the photoelectric effect, in the development of probes for surfaces. This effect offers the advantage of being contactless and nondestructive even at photon fluences at which nonlinear effects, such as two-photon photoemission processes, are observed. The probing of the energy band parameters at insulator/semiconductor buried interfaces is demonstrated. A study of the sensitivity of image-potential induced states upon temperature changes and atomic adsorption is presented, which leads to the uncovering of a new method to measure the temperature dependence of work functions on most metallic surfaces. Finally, a new, simple, photoemission scanning microscope is developed, which circumvents the need for energy-resolved techniques, for the mapping of doped regions on semiconductor surfaces. Dissert. Abstr.

DYNAMICS OF A COUPLED SOLID STATE LASER ARRAY Ph.D. Thesis
Larry Fabiny 1992 348 p
Avail: Univ. Microfilms Order No. DA9315875

The results of an investigation of the dynamic behavior of coupled solid state laser arrays are reported. Experimental results are compared with numerical simulations and analytic theory. Cavity designs for uncoupled and coupled arrays of Nd:YAG lasers are developed and experimental realizations of the arrays are fabricated. Spatially coupled Nd:YAG lasers are found to operate in stable phase-locked configurations, a result which is drastically different from the chaotic output present in semiconductor laser arrays. The phase-locking angle between adjacent lasers is observed to be pi radians, except when this angle is not possible for all nearest-neighbor pairs in the array. In that case, adjacent lasers phase lock with the relative angle nearest to pi that produces a self-consistent solution for the entire array. An analysis of the model rate equations for a coupled solid state laser array shows that stable phase-locked solutions for the Nd:YAG array are present for most values of the coupling coefficient. The same phase-locked solutions are unstable for semiconductor laser arrays, resulting in chaotic power fluctuations from individual lasing elements. The critical difference between semiconductor laser arrays and Nd:YAG laser arrays is the linewidth enhancement factor, which is significant only for the semiconductor lasers. The phase dynamics and mutual coherence of two spatially coupled Nd:YAG lasers are examined. A sharp transition from independent lasing to phase-locked out-of-phase lasing is observed as the separation distance between the lasers is reduced. The mutual coherence of the lasers is revealed by measuring the interference fringes formed by overlapping the output beams. A theoretical model that includes the relative frequency detuning of the two lasers makes predictions regarding the phase dynamics that are in excellent agreement with the experimental results. A nine-element Nd:YAG laser array coupled through diffractive feedback is fabricated. Self-feedback is observed to destabilize the output of a single Nd:YAG laser, thereby generating chaotic intensity fluctuations. When all nine lasers are operational, correlations between the intensity fluctuations of the lasers are seen. Small adjustments to the array cavity are sufficient to change the correlation from positive to negative. Dissert. Abstr.

LONGITUDINAL EFFECTS AND INTENSITY-PHASE COUPLING IN DISTRIBUTED FEEDBACK SEMICONDUCTOR LASERS Ph.D. Thesis
Lars Magnus Olofsson 1993 115 p
Avail: Univ. Microfilms Order No. DA9313874

The phenomenon of intensity-phase coupling in semiconductor lasers is investigated theoretically as well as experimentally for distributed feedback lasers. In addition, conditions for a uniform intensity profile are identified for such lasers. The theoretical study of intensity-phase coupling examines the importance of the longitudinal laser structure for this coupling exploiting a near threshold model. For the case of uniform gain and carrier density, no effect is expected from a periodic or quasi-periodic corrugation. On the other hand, when the gain-layer is corrugated or a gain-coupling mechanism is otherwise implemented, the influence may be considerable. It is shown that the degree of gain-coupling relative to index-coupling between right- and left-travelling waves and the specific mechanism by which variations in the carrier density influence this coupling are of key importance. We find that depending on the degree and nature of the gain-coupling, the strength of the intensity-phase coupling may be considerably reduced or enhanced. An interferometric method is wed to measure the coupling between intensity- and phase-modulation for 1.551 micron distributed feedback lasers for different bias and modulation frequency under small-signal modulation of the injection current. The strength of the measured intensity-phase coupling is quantified in terms of an effective chirp factor. We find this factor to increase monotonically and nearly double as the modulation frequency increases from below to above the resonance frequency of the relaxation oscillation. Our results contradict the commonly held view of the chirp factor as a constant parameter for a given laser structure. Simple conditions for a uniform intensity profile are presented for two kinds of center frequency DFB lasers. For a purely gain-coupled DFB laser the envelope of the intensity distribution is shown to be uniform when the spatially averaged gain constant is equal to zero. A second-order index-coupled laser structure with no second harmonic in its Fourier spectrum is predicted to lase precisely at the Bragg resonance and is shown to have a similar uniformity condition. For the special case of lasers with zero facet reflectivities, the condition is satisfied for both lasers when the product of the magnitude of the coupling constant and the length of the resonator is an odd integer multiple of pi/2. Dissert. Abstr.

Since the last report several things have happened to effect the research effort. In laser metrology, measurements using Michelson type interferometers with an FM modulated diode laser source have been performed. The discrete Fourier transform technique has been implemented. Problems associated with this technique as well as the overall FM scheme were identified. The accuracy of the technique is not at the level we would expect at this point. We are now investigating the effect of various types of noise on the accuracy as well as making changes to the system. One problem can be addressed by modifying the original optical layout. Our research effort was also expanded to include the assembly and testing of a diode pumpedNd:YAG laser pumpedTi sapphire laser for possible use in sounding rocket applications. At this stage, the diode pumped Nd:YAG laser has been assembled and made operational. Author (revised)

ADVANCES IN TUNABLE POWERFUL LASERS: THE ADVANCED FREE-ELECTRON LASER
S. Singer and R. Sheffield 1993 22 p Presented at the 11th International Workshop on Laser Interaction and Related Plasma Phenomena, Monterey, CA, 25-29 Oct. 1993
(Contract W-7405-eng-36)
(DE94-004997; LA-UR-93-4410; CONF-931048-2) Avail: CASI HC A03/MF A01

In the past several decades, remarkable progress in laser science and technology has made it possible to obtain laser light from the ultra-violet to the far infra-red from a variety of laser types and at power levels from milliwatts to kilowatts (and, some day, megawatts). However, the availabiiity of tunable lasers at 'high' power (above a few tens of watts) is more limited. An assessment of the availability of tunable lasers shows the covered range to be about 400 to 2000 nanometers. A variety of dye lasers cover the visible and near infrared, each one of which is tunable over approximately a 10% range. In the same region, the TI:sapphire laser is adjustable over a 20 to 25% range. And finally, optical parametric oscillators can cover the range from about 400 nanometers out to about 2000 nm (even farther at reduced energy output). The typical output energy per pulse may vary from a few to one hundred millijoules, and since repetition rates of 10 to 100 Hertz are generally attainable, average output

powers of tens of watts are possible. In recent years, a new approach to powerful tunable lasers--the Free-Electron Laser (FEL)--has emerged. In this paper we will discuss advances in FEL technology which not only enable tunability at high average power over a very broad range of wavelengths, but also make this device more usable. At present, that range is about one micron to the far infrared; with extensions of existing technology, it should be extendable to the vacuum ultraviolet region. DOE

Bright, spatially coherent x-ray lasers (XRL's) have applications in areas such as holography, interferometric imaging, and non-linear optics. Nominally, the authors can improve XRL coherence by either increasing the length or by reducing the aperture. Length can be increased by coupling multiple stages of XRL's or by using multilayer optics, but the effective gain length of an XRL is limited by refractive propagation and multilayer damages. The laser aperture is typically limited by the best-focused configuration defined by the driving optical lasers. Design of XRL's produced in exploding foil or slab configuration is further complicated by large spatial gain and n(sub e) inhomogeneities. This paper explores a new XRL design that uses the concept of adaptive spatial filtering by geometric shaping to improve the transverse coherence. One example of such shaped XRL's is a bowtie. The authors present here computational and experimental characterization of shaped XRL's during laser plasma expansion by studying their hydrodynamic behaviors, ionization histories, and laser output intensities. DEVELOPMENT OF HIGH TIME-RESOLUTION LASER FLASH EQUIPMENT FOR THERMAL DIFFUSIVITY MEASUREMENTS USING MINIATURE-SIZE SPECIMENS
Tatsuo Shikama (Tohoku Univ., Oarai, Japan.), Chusei Namba, Michinori Kosuda, and Yukio Maeda Jan. 1994 18 p Submitted for publication
(ISSN 0915-633X)
(NIFS-268) Avail: CASI HC A03/MF A01

For measurements of thermal diffusivity of miniature-size specimens heavily irradiated by neutrons, a new Q-switched laser-flash instrument was developed. In the present instrument the time resolution was improved to 0.1 ms by using a laser-pulse width of 25 ns. The realization of high time-resolution made it possible to measure the thermal diffusivity of thin specimens. It is expected that copper of 0.7mm thick, and SUS 304 of 0.1 mm could be used for the measurements. In case of ATJ graphite, 0.5mm thick specimen could be used for the reliable measurement in the temperature range of 300-1300K. Author

REACTOR-PUMPED LASER FACILITY AT DOE'S NEVADA TEST SITE
R. J. Lipinski 1994 8 p Presented at the OE/LASE 1994: Conference on Optics, Electro-Optics, and Laser Applications in Science and Engineering, Los Angeles, CA, 22-29 Jan. 1994
(Contract DE-AC04-94AL-85000)
(DE94-006371; SAND-94-0074C; CONF-940142-12) Avail: CASI HC A02/MF A01

The Nevada Test Site (NTS) is one excellent possibility for a laser power beaming site. It is in the low latitudes of the U.S., is in an exceptionally cloud-free area of the southwest, is already an area of restricted access (which enhances safety considerations), and possesses a highly-skilled technical team with extensive engineering and research capabilities from underground testing of our nation's nuclear deterrence. The average availability of cloud-free clear line of site to a given point in space is about 84%. With a beaming angle of +/- 60 degrees from the zenith, about 52 geostationary-orbit (GEO) satellites could be accessed continuously from NTS. In addition, the site would provide an average view factor of about 10% for orbital transfer from low earth orbit to GEO. One of the major candidates for a long-duration, high-power laser is a reactor-pumped laser being developed by DOE. The extensive nuclear expertise at NTS makes this site a prime candidate for utilizing the capabilities of a reactor pumped laser for power beaming. The site then could be used for many dual-use roles such as industrial material processing research, defense testing, and removing space debris. DOE

Recent advances in the development of reactor-pumped lasers (RPL's) have stimulated renewed interest in the concept of laser-powered propulsion. This paper surveys a number of laser propulsion concepts and identifies the one that is most promising from the standpoint of practicality. It is proposed that a ground-based FALCON (fission-activated laser concept) RPL can provide primary power for this launch vehicle design. The laser vehicle system could launch small payloads into low earth orbit (LEO) with high repetition rates and at low costs per kilogram. For the favored design, thruster efficiencies are currently estimated to be about 50 percent, with 80 percent being seen as a potentially realizable goal after further design refinements. Laser launch system simulations indicate that with a buy-in laser power of 10 MW, it will be possible to obtain specific impulses in the range of 600 to 800 seconds and payload-to-power ratios of 1 to 3 kg/MW. This report summarizes the results of a one year research program at the University of Michigan to investigate the physics and technology of microsecond electron beam diodes. These experiments were performed on the Michigan Electron Long Beam Accelerator (MELBA) at parameters: Voltage equals -0.65 to -0.9 MV, current equals 1 to 50 kA, and pulselength equals 0.5 to 5 microseconds. Major accomplishments include: (1) the first two-wavelength (CO2 and HeNe) laser deflection measurements of diode plasma and neutrals; (2) measurements of the effects on magnetic field gradient on microsecond diode closure; (3) demonstration of good fidelity of processed x-ray signals as a diagnostic of beam voltage; (4) extended-pulselength scaling of electron beam diode arcing and diode closure; and (5) innovative Cerenkov plate diagnostics of e-beam dynamics. NONLINEAR ABSORPTION IN HIGH REFLECTOR MULTILAYERS
C. J. Stolz, T. G. Sarginson, and J. R. Taylor Nov. 1993 12 p Presented at the 25th Boulder Damage Symposium: Annual Symposium on Optical Materials for High-Power Lasers, Boulder, CO, 27-29 Oct. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-005818; UCRL-JC-114983; CONF-931054-6) Avail: Issuing Activity (Department of Energy (DOE))

Low absorption coatings were examined using a high repetition rate copper vapor laser to study the surface temperature as a function of incident power. Nonlinear absorption was observed in some of the coatings as a result of increased incident power. A variety of commercial coating vendors using common dielectric oxide material combinations were surveyed. Wavelength, coating material, and coating vendor were varied to study their effects on the linearity of the absorption. The films were deposited

by electron beam or ion beam sputtering technologies. Changes in the film characteristics were observed after exposure to high incident power. The nature of these changes and their permanency were also examined. DOE

REMOTE PUMPING OF SOLID STATE LASERS WITH NUCLEAR DRIVEN FLUORESCERS
M. A. Prelas 30 Nov. 1993 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG02-90ER-13029)
(DE94-004846; DOE/ER-13029/T3) Avail: CASI HC A03

Development of an electron density model, microwave propagation model, and power density model was completed for various visible excimer gas media including the xenon oxide excimer (XeO*). In addition, a heat transfer model was developed. Optimization of a microwave pumped excimer lamp has begun and the results indicate that high frequency modes can be excited efficiently. A model for power density in the cavity has been developed and indicates that 111 modes appear to be the most uniform. A He3 excited nuclear 'pumped' lamp was built to take spectra of gas mixtures in a reactor environment. The effects of nuclear radiation on optical materials was examined from 350 nm to 950 nm. The results demonstrated that radiation effects are nonlinear with power. Additionally, radiation damage was strongest in the UV bandwidth. Studies were also made of radiation induced fluorescence. A method was developed to subtract radiation induced fluorescence from the fluorescence signal in the lamp. Using the results of radiation induced absorption and radiation induced fluorescence, a technique for determining absolutely calibrated spectra from the lamp was developed. Absolutely calibrated spectra from He, He-Ar, He-Xe, and He-Kr were taken. The results from this study were compared to electrically driven flashlamps. A heat pipe for a reactor experimentation with alkali metals was developed. Several experiments were run using the heat pipe filled with 5 grams of sodium. Radiation from the violet bands of sodium at around 436 nm was expected. Indeed observations of emission at 436 nm were made. The overall results of this work were: (1) development of a microwave excitation system which approximated nuclear 'pumping'; (2) development of methods to compensate for radiation induced absorption and radiation induced fluorescence in optical systems in high radiation environments; and (3) development of methods to obtain absolutely calibrated spectra from light. TOWARDS SHORT WAVELENGTHS FELs WORKSHOP
I. Ben-Zvi and H. Winick 1993 98 p Workshop held in Upton, NY, 21-22 May 1993
(Contract DE-AC02-76CH-00016)
(DE94-004346; BNL-49651; CONF-9305307) Avail: CASI HC A05/MF A02

This workshop was caged because of the growing perception in the FEL source community that recent advances have made it possible to extend FEL operation to wavelengths about two orders of magnitude shorter than the 240 nm that has been achieved to date. In addition short wavelength FEL's offer the possibilities of extremely high peak power (several gigawatts) and very short pulses (of the order of 100 fs). Several groups in the USA are developing plans for such short wavelength FEL facilities. However, reviewers of these plans have pointed out that it would be highly desirable to first carry out proof-of-principle experiments at longer wavelengths to increase confidence that the shorter wavelength devices will indeed perform as calculated. The need for such experiments has now been broadly accepted by the FEL community. Such experiments were the main focus of this workshop as described in the following objectives distributed to attendees: (1) Define measurements needed to gain confidence that short wavelength FEL's will perform as calculated. (2) List possible hardware that could be used to carry out these measurements in the near term. (3) Define a prioritized FEL physics experimental program and suggested timetable. (4) Form collaborative teams to carry out this program. DOE

THE DEVELOPMENT AND EVALUATION OF A TUNABLE DIODE LASER TRACE GAS SENSOR FOR THE MEASUREMENT OF N2O AND CH4 FLUXES USING MICROMETEOROLOGICAL TECHNIQUES Ph.D. Thesis
Grant Carleton Edwards 1992 123 p
(ISBN-0-315-78975-1) Avail: Univ. Microfilms Order No. DANN78975

A sensitive fast response fieldworthy trace gas sensor, based on tunable diode laser absorption spectroscopy, has been successfully developed for the measurement of the exchange of methane or nitrous oxide between a surface and the atmosphere using micrometeorological techniques. The instrument has been proven to be suitable for the reliable continuous measurement of the flux of methane or nitrous oxide. This development is a significant advance over other techniques for the measurement of the fluxes of trace gases. The instrument developed has a total system noise of less than 5 ppbv rms for CH4 and better than 2 ppbv rms for N2O with an effective bandwidth of 0.001 to 1.6 Hz. The system sampling rate of 10 Hz, was determined by a 0.18 data point averaging time. The instrument was developed through extensive field testing involving the continuous measurement of nitrous oxide and methane fluxes in forest and wetland ecosystems respectively. Measurements of N2O fluxes from a deciduous forest were made with a first generation instrument using a tower based eddy correlation approach. Instrument performance was sufficient to obtain a limited data set on the emission of N2O from a deciduous forest during an 'Indian Summer' event during the fall of 1989. These data showed an average daytime emission of 119 ng m(exp -2)/s of N2O. On average, measured values fell below the estimated detection limit of 40 ng m(exp -2)/s during the evening. The data suggested that the forest can be a significant natural source of N2O. The results emphasizes the need for continuous high time resolution data on N2O emission from natural ecosystems before rational global budgets can be constructed. Based on the operating experience during this field study, improvements to the optical, electronic and digital signal processing systems were implemented. With a second generation TDL sensor, tower based eddy correlation measurements of the methane fluxes were made above a wetland. Approximately 900 half hour average methane flux measurements were obtained during a 30 day period in July, 1990. Fluxes averaged over the study period showed an overall methane emission of 16 mg m(exp -2)/d with a daytime average of 20 mg m(exp -2)/d and a nighttime average of 9 mg m(exp -2)/d. The effect of heterogeneous surface emissions were evident in the data. A strong relationship between the daily average methane flux and wet bog temperature at 20 cm depth was observed.

DIODE-PUMPED SOLID-STATE-LASER DRIVERS AND THE COMPETITIVENESS OF INERTIAL FUSION ENERGY
C. D. Orth Dec. 1993 12 p Presented at the 11th International Workshop on Laser Interaction and Related Plasma Phenomena, Monterey, CA, 25-29 Oct. 1993
(Contract W-7405-eng-48)
(DE94-006654; UCRL-JC-114902; CONF-931048-5) Avail: CASI HC A03/MF A01

Based on five technical advances at LLNL and a new systems-analysis code, we present conceptual designs for diode-pumped solid state laser (DPSSL) drivers for inertial fusion energy (IFE) power plants. Such designs are based on detailed physics calculations for the drive and on generic scaling relationships for the reactor and balance of plant (BOP). We describe the performance and economics of such power plants, show how sensitive these results are to changes in the major parameters, and indicate how technological improvements can make DPSSL-driven IFE plants more competitive. (DE94-005265; IS-T-1657) Avail: CASI HC A06/MF A02

Matrix-assisted laser desorption (MALD) is a technique for converting large biomolecules into gas phase ions. Some characteristics of the commonly used uv matrices are determined. Solubilities in methanol range from 0.1 to 0.5 M. Solid phase absorption spectra are found to be similar to solution, but slightly red-shifted. Acoustic and quartz crystal microbalance signals are investigated as possible means of uv-MALD quantitation. Evidence for the existence of desorption thresholds is presented. Threshold values are determined to be in the range of 2 to 3 MW/sq cm. A transient

imaging technique based on laser-excited fluorescence for monitoring MALD plumes is described. Sensitivity is well within the levels required for studying matrix-assisted laser desorption, where analyte concentrations are significantly lower than those in conventional laser desorption. Results showing the effect of film morphology, particularly film thickness, on plume dynamics are presented. In particular, MALD plumes from thicker films tend to exhibit higher axial velocities. Fluorescent labeling of protein and of DNA is used to allow imaging of their uv-MALD generated plumes. Integrated concentrations are available with respect to time, making it possible to assess the rate of fragmentation. The spatial and temporal distributions are important for the design of secondary ionization schemes to enhance ion yields and for the optimization of ion collection in time-of-flight MS instruments to maximize resolution. Such information could also provide insight into whether ionization is closely associated with the desorption step or whether it is a result of subsequent collisions with the matrix gas (e.g., proton transfer). Although the present study involves plumes in a normal atmosphere, adaptation to measurements in vacuum (e.g., inside a mass spectrometer) should be straightforward. DOE

JOINING SILICON CARBIDE TO AUSTENITIC STAINLESS STEEL THROUGH DIFFUSION WELDING Ph.D. Thesis
J. P. H. M. Krugers 19 Jan. 1993 186 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-126331) Avail: CASI HC A09

In the thesis, the results are presented of a study dealing with joining silicon carbide to austenitic stainless steel AISI316 by means of diffusion welding. Welding experiments were carried out with and without the use of a metallic intermediate, like copper, nickel, and copper-nickel alloys at various conditions of process temperature, process time, mechanical pressure, and interlayer thickness. Most experiments were carried out in high vacuum. For reasons of comparison, however, some experiments were also carried out in a gas shielded environment of 95% vol. Ar and 5% vol. H2. NTIS

The purpose of this report is to document the status of the Mechanical Flexible Joint (MFJ) Design Subtask with the intent of halting work on the design. Recommendations for future work is included in the case that the task is to be resumed. The MFJ is designed to eliminate two failure points from the current flex joint configuration, the inner 'tripod configuration' and the outer containment jacket. The MFJ will also be designed to flex 13.5 degrees and have three degrees of freedom. By having three degrees of freedom, the MFJ will allow the Low Pressure Fuel Duct to twist and remove the necessity to angulate the full 11 degrees currently required. The current flex joints are very labor intensive and very costly and a simple alternative is being sought. The MFJ is designed with a greater angular displacement, with three degrees of freedom, to reside in the same overall envelope, to meet weight constraints of the current bellows, to be compatible with cryogenic fuel and oxidizers, and also to be man-rated. Since the discovery of high temperature superconductors (HTS's), Argonne National Laboratory (ANL) has been active in a broad spectrum of activities in developing these materials for applications. Work at every stage of development has involved industrial collaboration in order to accelerate commercialization. While most of the development work has been devoted to improving the properties of current-carrying wires, some effort has been devoted to applications that can utilize HTS's with properties available now or in the near future. In this paper, advances made in the area of current leads and magnetic bearings are discussed. DOE

In this study, after reviewing current seal design concepts, the potential of textile structures for seal design is examined from the material, structural, and fabrication points of view. Braided structures are identified as potential candidates for hypersonic seal structures because of their conformability and design flexibility. A large family of braided structures using 2-D and 3-D architecture can be designed using well established methods to produce a wide range of braiding yarn orientation for wear resistance as well as seal porosity control. As a first demonstration of the approach, 2-D braided fiberglass seals were fabricated according to a factorial design experiment by varying braiding angles, fractional longitudinal fibers, and preload pressure levels. Factorial diagrams and response surfaces were constructed to elucidate the inter-relationship of the braiding parameters as well as the effect of preload pressures on leakage resistance of the seal. It was found that seal resistance is a strong function of fractional longitudinal fiber content. As braiding angle increases, seal leakage resistance increases, especially at high preload pressures and in seals having high proportion of longitudinal fibers. Author (revised)

DESIGN AND CONSTRUCTION OF THE AEROBOT ROBOTIC MANIPULATOR (ARM) M.S. Thesis
William L. Cochran Dec. 1993 118 p
(AD-A275362; AFIT/GA/ENY-93D-2) Avail: CASI HC A06/MF A02

This thesis designed, constructed, and tested a robotic arm for the Aerobot (Aerial Robot). The main purpose of the ARM is to enable the Aerobot to retrieve objects during an annual robotics competition. Design of the ARM involved synthesizing the characteristics of simplicity, weight, strength, and size. The result was a three-degree-of-freedom manipulator that uses electric motors, cable linkages, and telescoping tubes to access a work space below the Aerobot. Forward and inverse kinematics were investigated to enable automation of the ARM. Data was collected from infrared sensors to validate the model. Manipulation of the ARM is presently under open loop control (joy stick) which demonstrates the use of tele-robotics and its capabilities. DTIC

ATOMIC-SCALE FRICTION MEASUREMENTS USING FRICTION FORCE MICROSCOPY. PART 2: APPLICATION TO MAGNETIC MEDIA
Bharat Bhushan and Ju-Ai Ruan 3 May 1993 39 p
(AD-A275202) Avail: CASI HC A03/MF A01

Atomic Force/Friction Force Microscopes (AFM/FFM) were used to study tribological properties of metal-particle tapes with two roughnesses, Co-gamma Fe2O3 tapes (unwiped and wiped), and unlubricated and lubricated thin-film magnetic rigid disks (as-polished and standard textured). Nanoindentation studies showed that the hardness of the tapes through the magnetic coating is not uniform. These results are consistent with the fact that the tape surface is a composite and is not homogeneous. Nanoscratch experiments performed on magnetic tapes using silicon nitride tips revealed that deformation and displacement of tape surface material occurred after one pass under light loads (approx. 100 nN). A comparison between friction force profiles and the corresponding surface roughness profiles of all samples tested shows a poor correlation between localized values of friction and surface roughness. Detailed studies of friction and surface profiles demonstrate an excellent correlation between localized variation of the slope of the surface roughness along the sliding direction and the localized variation of friction. Atomic-scale friction in magnetic media and natural diamond appears to be due to adhesive and ratchet (roughness) mechanisms. Directionality in the local variation of atomic-scale friction data was observed as the samples were scanned in either direction, resulting from the scanning direction and the anisotropy in the surface topography. Atomic-scale coefficient of friction is generally found to be smaller than the macrocoefficient of friction as there may be less ploughing contribution in atomic-scale measurements. DTIC

TUNED MASS DAMPER FOR INTEGRALLY BLADED TURBINE ROTOR Patent Application
John J. Marra, inventor (to NASA) (Pratt and Whitney Aircraft, West Palm Beach, FL.) 12 Oct. 1993 12 p
(NASA-Case-MFS-28697-1; NAS 1.71:MFS-28697-1;
US-Patent-Appl-SN-134443) Avail: CASI HC A03/MF A01

The invention is directed to a damper ring for damping the natural vibration of the rotor blades of an integrally bladed rocket turbine rotor. The invention consists of an integral damper ring which is fixed to the underside of the rotor blade platform of a turbine rotor. The damper ring includes integral supports which extend radially outwardly therefrom. The supports are located adjacent to the base portion and directly under each blade of the rotor. Vibration damping is accomplished by action of tuned mass damper beams attached at each end to the supports. These beams vibrate at a predetermined frequency during operation. The vibration of the beams enforce a local node of zero vibratory amplitude at the interface between the supports and the beam. The vibration of the beams create forces upon the supports which forces are transmitted through the rotor blade mounting platform to the base of each rotor blade. When these forces attain a predetermined design frequency and magnitude and are

directed to the base of the rotor blades, vibration of the rotor blades is effectively counteracted. NASA

LUNAR SURFACE OPERATIONS. VOLUME 1: LUNAR SURFACE EMERGENCY SHELTER Annual Report
William Shields, Salah Feteih, and Patrick Hollis Jul. 1993 174 p
(Contract NASw-4435)
(NASA-CR-195551; NAS 1.26:195551) Avail: CASI HC A08/MF A02

The lunar surface emergency shelter (LSES) is designed to provide survival-level accommodations for up to four astronauts for a maximum of five days. It would be used by astronauts who were caught out in the open during a large solar event. The habitable section consists of an aluminum pressure shell with an inner diameter of 6 ft. and a length of 12.2 ft. Access is through a 4 in. thick aluminum airlock door mounted at the rear of the shelter. Shielding is provided by a 14.9 in. thick layer of lunar regolith contained within a second, outer aluminum shell. This provides protection against a 200 MeV event, based on a 15 REM maximum dose. The shelter is self-contained with a maximum range of 1000 km. Power is supplied by a primary fuel cell which occupies 70.7 cu ft. of the interior volume. Mobility is achieved by towing the shelter behind existing lunar vehicles. It was assumed that a fully operational, independent lunar base was available to provide communication support and tools for set-up and maintenance. Transportation to the moon would be provided by the proposed heavy lift launch vehicle. Major design considerations for the LSES were safety, reliability, and minimal use of earth materials. APPARATUS FOR TESTING HIGH PRESSURE INJECTOR ELEMENTS Patent Application
William Neill Myers, inventor (to NASA), Ewell M. Scott, inventor (to NASA), John C. Forbes, inventor (to NASA), and Michael D. Shadoan, inventor (to NASA) 7 Sep. 1993 19 p
(NASA-Case-MFS-28773-1; NAS 1.71:MFS-28773-1;
US-Patent-Appl-SN-117587) Avail: CASI HC A03/MF A01

An apparatus for testing and evaluating the spray pattern of high pressure fuel injector elements for use in supplying fuel to combustion engines is presented. Prior art fuel injector elements were normally tested by use of low pressure apparatuses which did not provide a purge to prevent mist from obscuring the injector element or to prevent frosting of the view windows; could utilize only one fluid during each test; and had their viewing ports positioned one hundred eighty (180 deg) apart, thus preventing optimum use of laser diagnostics. The high pressure fluid injector test apparatus includes an upper hub, an upper weldment or housing, a first clamp and stud/nut assembly for securing the upper hub to the upper weldment, a standoff assembly within the upper weldment, a pair of window housings having view glasses within the upper weldment, an injector block assembly and purge plate within the upper weldment for holding an injector element to be tested and evaluated, a lower weldment or housing, a second clamp and stud/nut assembly for securing the lower weldment to the upper weldment, a lower hub, a third clamp and stud/nut assembly for securing the lower hub to the lower weldment, mechanisms for introducing fluid under high pressure for testing an injector element, and mechanisms for purging the apparatus to prevent frosting of view glasses within the window housings and to permit unobstructed viewing of the injector element. A rotary blood pump is presented. The pump includes a pump housing for receiving a flow straightener, a rotor mounted on rotor bearings and having an inducer portion and an impeller portion, and a diffuser. The entrance angle, outlet angle, axial, and radial clearances of the blades associated with the flow straightener, inducer portion, impeller portion, and diffuser are optimized to minimize hemolysis while maintaining pump efficiency. The rotor bearing includes a bearing chamber that is filled with crosslinked blood or other bio-compatible material. A back emf integrated circuit regulates rotor operation and a microcomputer may be used to control one or more back emf integrated circuits. A plurality of magnets are disposed in each of a plurality of impeller blades with a small air gap. A stator may be axially adjusted on the pump housing to absorb bearing load and maximize pump efficiency. NASA

LUNAR SURFACE OPERATIONS. VOLUME 4: LUNAR ROVER TRAILER Annual Report
William Shields, Salah Feteih, and Patrick Hollis Jul. 1993 77 p
(Contract NASw-4435)
(NASA-CR-195554; NAS 1.26:195554) Avail: CASI HC A05/MF A01

The purpose of the project was to design a lunar rover trailer for exploration missions. The trailer was designed to carry cargo such as lunar geological samples, mining equipment and personnel. It is designed to operate in both day and night lunar environments. It is also designed to operate with a maximum load of 7000 kilograms. The trailer has a ground clearance of 1.0 meters and can travel over obstacles 0.75 meters high at an incline of 45 degrees. It can be transported to the moon fully assembled using any heavy lift vehicle with a storage compartment diameter of 5.0 meters. The trailer has been designed to meet or exceed the performance of any perceivable lunar vehicle. Author

Three constituents of the Martian atmosphere, methane, carbon dioxide, and oxygen, can be used for internal combustion in engines utilized for future space exploration on Mars. These three gases, considered as the test case in this research, will be examined to determine required flow rates needed for combustion and optimization of engine performance. Results of the test case are examined in relation to a base case of methane and air for comparative purposes. Testing of exhaust temperatures, cylinder pressure, and exhaust gas analysis were performed for the base case and test case. Also described is a study utilizing a zirconia cell to convert carbon dioxide into usable oxygen to help support future Mars missions. Derived from text

AN EMERGENCY RESPONSE MOBILE ROBOT FOR OPERATIONS IN COMBUSTIBLE ATMOSPHERES Patent Application
Henry W. Stone, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) and Timothy R. Ohm, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena.) 15 Nov. 1993 21 p
(Contract NAS7-918)
(NASA-Case-NPO-19020-1-CU; NAS 1.71:NPO-19020-1-CU;
US-Patent-Appl-SN-153934) Avail: CASI HC A03/MF A01

A mobile, self-powered, self-contained, and remote-controlled robot is presented. The robot is capable of safely operating in a combustible atmosphere and providing information about the atmosphere to the operator. The robot includes non-sparking and non-arcing electro-mechanical and electronic components designed to prevent the robot from igniting the combustible atmosphere. The robot also includes positively pressurized enclosures that house the electromechanical and electronic components of the robot and prevent intrusion of the combustible atmosphere into the enclosures. The enclosures are interconnected such that a pressurized gas injected into any one of the enclosures is routed to all the other enclosures through the interconnections. It is preferred that one or more sealed internal channels through structures intervening between the enclosures be employed. Pressure transducers for detecting if the pressure within the enclosures falls below a predetermined level are included. The robot also has a sensing device for determining the types of combustible substances in the surrounding atmosphere, as well as the concentrations of each type of substance relative to a pre-determined lower explosive limit (LEL). In addition, the sensing device can determine the percent level of oxygen present in the surrounding atmosphere. NASA

Service equipment for use in hostile environments is presented. The equipment includes a detachable service unit secured to a stationary service unit. The detachable service unit includes a housing with an exterior plate, a power control interface for connection to an exterior power source, locating pins located in said exterior plate, an electrical connector in the exterior plate electrically coupled to said power control interface, and a pair of clamping receptacles formed in the exterior plate and located on adjacent opposite edges of the exterior plate. The stationary unit includes an electrical connector for connection to the electrical connector of the detachable service unit, a clamping apparatus for clamping and unclamping the detachable service unit from the stationary unit, a base clamp assembly for mounting the clamping apparatus onto the stationary unit, and locating pin holes for receiving the locating pins and aligning the detachable service unit onto the stationary unit. The detachable service unit have mating scalloped faces which aid in alignment and provide a mechanism for heat dissipation. Official Gazette of the U.S. Patent and Trademark Office

US-Patent-Class-248-205.3; Int-Patent-Class-E05B-1/00) Avail: US Patent and Trademark Office

A portable hand-grip device for use during extravehicular activity is described. The device has a base member overlaid by a flexible pad having its opposite end releasably secured to the base. The pad includes an adhesive-covered surface which may be attached to a flat surface. A plurality of closely-spaced elongated rigid members are arranged side-by-side across the back of the flexible sheet to reinforce the flexible pad. The ends of these reinforcing members project beyond the opposite sides of the base and flexible pad. A selectively-operable mechanism on the base member releasably captures the outer end of the reinforcing members and secures them when the pad member is attached to a flat surface and provides a load path between a handle on the base and the flexible pad. The selectively-operable mechanism is further arranged to selectively release the reinforcing members so that the device may be progressively peeled away from a wall surface.

WELDING WIRE PRESSURE SENSOR ASSEMBLY Patent

Timothy B. Morris, inventor (to NASA), Peter F. Milly, Sr., inventor (to NASA), and J. Kevin White, inventor (to NASA) 12 Apr. 1994 6 p Filed 27 May 1993 Supersedes N93-28951 (31 - 11, p 3442)
(NASA-Case-MFS-26216-1-SB; US-Patent-5,302,805;
US-Patent-Appl-SN-070132; US-Patent-Class-219-137.71;
Int-Patent-Class-B23K-9/12) Avail: US Patent and Trademark Office

The present invention relates to a device which is used to monitor the position of a filler wire relative to a base material being welded as the filler wire is added to a welding pool. The device is applicable to automated welding systems wherein nonconsumable electrode arc welding processes are utilized in conjunction with a filler wire which is added to a weld pool created by the electrode arc. The invention senses pressure deviations from a predetermined pressure between the filler wire and the base material, and provides electrical signals responsive to the deviations for actuating control mechanisms in an automatic welding apparatus so as to minimize the pressure deviation and to prevent disengagement of the contact between the filler wire and the base material.

CFD ANALYSES FOR ADVANCED PUMP DESIGN Final Report

F. J. deJong, S.-K. Choi, and T. R. Govindan Apr. 1994 57 p Original contains color illustrations

(Contract NAS8-38866)
(NASA-CR-194866; NAS 1.26:194866; R94-9081-F) Avail: CASI HC A04/MF A01; 23 functional color pages

As one of the activities of the NASA/MSFC Pump Stage Technology Team, the present effort was focused on using CFD in the design and analysis of high performance rocket engine pumps. Under this effort, a three-dimensional Navier-Stokes code was used for various inducer and impeller flow field calculations. An existing algebraic grid generation procedure was-extended to allow for nonzero blade thickness, splitter blades, and hub/shroud cavities upstream or downstream of the (main) blades. This resulted in a fast, robust inducer/impeller geometry/grid generation package. Problems associated with running a compressible flow code to simulate an incompressible flow were resolved; related aspects of the numerical algorithm (viz., the matrix preconditioning, the artificial dissipation, and the treatment of low Mach number flows) were addressed. As shown by the calculations performed under the present effort, the resulting code, in conjunction with the grid generation package, is an effective tool for the rapid solution of three-dimensional viscous inducer and impeller flows.

EXPERIMENTAL VALIDATION OF FINITE ELEMENT AND BOUNDARY ELEMENT METHODS FOR PREDICTING STRUCTURAL VIBRATION AND RADIATED NOISE Final Report
A. F. Seybert, T. W. Wu, and X. F. Wu Jan. 1994 94 p Original contains color illustrations
(Grant NAG3-912; DA Proj. 1L1-62211-A-47A; RTOP 505-62-10)
(NASA-CR-4561; ARL-CR-109; E-8264; NAS 1.26:4561) Avail: CASI HC A05/MF A01; 3 functional color pages

This research report is presented in three parts. In the first part, acoustical analyses were performed on modes of vibration of the housing of a transmission of a gear test rig developed by NASA. The modes of vibration of the transmission housing were measured using experimental modal analysis. The boundary element method (BEM) was used to calculate the sound pressure and sound intensity on the surface of the housing and the radiation efficiency of each mode. The radiation efficiency of each of the transmission housing modes was then compared to theoretical results for a finite baffled plate. In the second part, analytical and experimental validation of methods to predict structural vibration and radiated noise are presented. A rectangular box excited by a mechanical shaker was used as a vibrating structure. Combined finite element method (FEM) and boundary element method (BEM) models of the apparatus were used to predict the noise level radiated from the box. The FEM was used to predict the vibration, while the BEM was used to predict the sound intensity and total radiated sound power using surface vibration as the input data. Vibration predicted by the FEM model was validated by experimental modal analysis; noise predicted by the BEM was validated by measurements of sound intensity. Three types of results are presented for the total radiated sound power: sound power predicted by the BEM model using vibration data measured on the surface of the box; sound power predicted by the FEM/BEM model; and sound power measured by an acoustic intensity scan. In the third part, the structure used in part two was modified. A rib was attached to the top plate of the structure. The FEM and BEM were then used to predict structural vibration and radiated noise respectively. The predicted vibration and radiated noise were then validated through experimentation.

A six degree of freedom parallel manipulator having three inextensible limbs for manipulating a platform is described in which the three inextensible limbs are attached via universal joints to the platform at noncollinear points. Each of the inextensible limbs is also attached via universal joints to a two degree of freedom parallel driver such as a five-bar linkage, a pantograph, or a bidirectional linear stepper motor. The drivers move the lower ends of the limbs parallel to a fixed base and thereby provide manipulation of the platform. The actuators are mounted on the fixed base without using any power transmission devices such as gears or belts.

COMBUSTION AND HEAT TRANSFER IN A HIGH SPEED DIESEL ENGINE OPERATING WITH RAPE SEED OIL METHYL ESTER FUEL
R. Turunen 1994 68 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB94-137536; ISBN-951-22-1710-4) Avail: CASI HC A04

The properties of RME (rape seed oil methyl ester) as a fuel for a diesel engine have been investigated theoretically and experimentally. The experiments were made with a turbocharged high-speed DI engine. During experiments the specific fuel consumption, exhaust gas emissions, heat release rate, flame temperature and the temperatures of the combustion chamber walls were measured. A test was also made using the measured flame temperature as an initial value for a two-zone combustion model. The theoretical investigations show that it is possible to achieve with RME approximately the same power as with ordinary diesel fuel from the same cylinder volume. The fuels give very similar theoretical (ideal) working cycles and also the efficiencies of the cycles are very near to each other. NTIS

KINEMATIC REPRESENTATIONS, WORKSPACE ANALYSIS, AND GRASP STABILITY IN ROBOT ARMS AND MULTI-FINGERED HANDS Ph.D. Thesis
Fu-Hua Jen 1992 123 p
Avail: Univ. Microfilms Order No. DA9313618

This work studies three related aspects of robotics: the set of possible kinematic representations of robot motion, the range of all possible robot positions, i.e., the workspace, and the designing of stable grasps with a multifingered end-effector. A survey of alternatives to the homogeneous transformation to represent robot coordinate translations and rotations is given. The advantages and disadvantages of each are discussed, and their computational complexities are compared, giving the number of arithmetic operations required by the different methods. In viewing rigid body motions, two aspects are considered: point transformations, which result in matrix-based transformations, and line transformations, which result in screw-based transformations. Algebraic expressions for the robot workspace are helpful in the design of robots. Here, a complete methodology is developed to obtain algebraic expressions to aid robot workspace construction, based on the analysis of Jacobian matrices. Reduction of the complexity of the workspace analysis is achieved by choice of the coordinate system used in the representation. It is shown that, in the worst case 2 x 2 submatrices of the Jacobian need to be checked, and with some specific kinematic structures, it is sufficient to examine only a set of scalar expressions. Examples of using algebraic expressions to generate workspace without mechanical limitations are given. The third part of this work represents the first application of Liapunov stability theory of differential equations to

the problem of generating stable grasps of an object with a multifingered hand. The analysis of grasp stability where finger forces are maintained constant is considered, as well as certain modified force control laws that introduce damping. In the robotics community there is considerable research emphasis related to the use of force control methods rather than the usual position control, and this motivates the study. Stability theory for nonlinear differential equations is applied to establish the conditions on finger locations and grasp force directions that are associated with Liapunov stability, with asymptotic stability, and with instability of grasps. Relationships are given between these mathematical concepts and various desirable properties of grasp that have previously been used in defining various concepts of stable grasp. A geometrical representation of the stability condition is given which assists the synthesis of the grasp, and examples in two and three dimensions are given. Dissert. Abstr.

N94-29870 Texas A&M Univ., College Station.
A DESIGN METHODOLOGY FOR SYNTHESIZING LOW-ORDER ROBUST CONTROLLERS FOR FLEXIBLE STRUCTURES Ph.D. Thesis
Byung-Keun Song 1992 204 p
Avail: Univ. Microfilms Order No. DA9315147

A design methodology is developed for realizing low order robust controllers for flexible structures modelled as partial differential equations (PDE's). The efficacy of the methodology is illustrated by synthesizing robust controllers for a free-free beam system and a flexible robot link system. The performance of these controllers is evaluated in simulations and in actual implementation on a flexible robot link set up. Reduced (finite) order models are frequently used in designing controllers for flexible structures due to their simplicity. They often lead to control spillover effects which tend to degrade the performance or even destabilize. The control spillover can be completely removed only by designing a controller based on a full (infinite) order model. Recently, full order models have been used for designing controllers by modern robust control design techniques such as H(sub infinity) and H(sub 2). However, the resulting controllers from these techniques typically have excessively high orders since the optimization involved calls for a systematic cancellation of the stable poles and zeros of the plant. The design methodology proposed here is an outgrowth of the standard quantitative feedback theory (QFT) and utilizes the closed form irrational transfer function obtained from an infinite-dimensional model described by hyperbolic PDE's. Although standard QFT has many attractive features such as its capacity to deal with parametric plant uncertainty and cost of feedback, the loop-shaping procedure is not necessarily straightforward. Hence when the standard QFT procedure is applied to these infinite order plants, the loop-shaping procedure becomes even more difficult. The proposed methodology alleviates this by converting the loop-shaping procedure for an infinite order plant into that of a finite order plant by introducing a finite order quasi-nominal plant. In spite of the challenging loop-shaping task, the method provides enough transparency for one to customize the controllers by trading off some design specifications to achieve more practical or realizable controllers. Dissert. Abstr.

N94-29884 Purdue Univ., West Lafayette, IN.
COLLISION AVOIDANCE AND CONTROL OF MULTIPLE REVOLUTE MANIPULATORS Ph.D. Thesis
Zohreh Erfan 1992 120 p
Avail: Univ. Microfilms Order No. DA9313979

In Chapter 1, a survey on collision avoidance for multirobot systems is presented. In Chapter 2, the problem of path planning for a revolute two-link arm, operating in a workspace filled with obstacles whose boundaries are enveloped by circles or possibly any other shape, is addressed. The path planning approach presented in this chapter is developed in the manipulator joint space and consists of two strategies. The first strategy is used in tightly packed free spaces located between the workspace obstacles; this approach relies on constrained optimization. The second strategy is used whenever the manipulator is operating in any free space region far from the workspace obstacles; this strategy does not use optimization but relies on a global but safe approximation of the free regions of the joint space. This division of the path planning approach reduces the chances that the manipulator will get stuck in a geometrical local minimum during the planning procedure, compared to what would likely happen if the first strategy is used throughout the entire path planning procedure. With the approach taken here, the chance of finding a path for the manipulator from its given start point to its desired goal point in an automated manner is high in comparison to one which uses just one of the two approaches. In Chapter 3, the problem of path planning and control of multiple robots operating in a common workspace is addressed. The developments in this chapter merge the control and trajectory planning issues for obstacle avoidance into one. An on-line control law has been determined which avoids collisions between the arms while guiding the end-effectors from their respective starting positions S to their respective desired goal positions G, if such a collision free trajectory exists. The control law is determined from a Lyapunov function based on the total system energy. Simulation results are presented which show that the control scheme developed in this chapter is able to guide two manipulators working in a common workspace avoid collisions with each other as they reach their goal points. No off-line path planning involving geometric analysis is necessary for this scheme to work if a collision free trajectory is feasible. Dissert. Abstr.

N94-29916 Texas A&M Univ., College Station.
ROTORDYNAMIC ANALYSIS OF ANNULAR HONEYCOMB-STATOR TURBULENT GAS SEALS USING A NEW FRICTION-FACTOR MODEL BASED ON FLAT PLATE TESTS Ph.D. Thesis
Tae Woong Ha 1992 193 p
Avail: Univ. Microfilms Order No. DA9315067

A flat plate tester with various honeycomb geometries has been extended to develop a better understanding of the friction-factor behavior of honeycomb surfaces. The friction-factor-jump phenomenon, which is characterized by the dramatic drop and then rise of the friction-factor with increasing Reynolds number, has been explained by acoustic excitation of a large scale coherent flow structure from pressure fluctuation measurements inside the honeycomb cavities. A new friction-factor model based on the flat-plate-test results has been developed as a function of Mach number, dimensionless pressure, and honeycomb geometry variables. A rotordynamic analysis has been developed for centered, turbulent-annular honeycomb-stator seals incorporating the new empirical friction-factor model for honeycomb-stator surfaces. The validity of the new analysis in predicting the rotordynamic and leakage characteristics has been compared to Moody's friction-factor model analysis and experimental data for a short (L/D = 1/6, 25.4 mm long) seal and a longer (L/D = 1/3, 50.8 mm long) seal. The comparisons show that the new honeycomb friction-factor model greatly improves the predictions of leakage and rotordynamic coefficients compared to Moody's friction-factor model for both the short and longer seal, especially, for direct stiffness and cross-coupled stiffness. The new honeycomb friction-factor model predicts leakage and rotordynamic coefficients better for the short than the longer seals. Dissert. Abstr.

ANALYSIS OF DATA FROM ELECTRIC AND HYBRID ELECTRIC VEHICLE STUDENT COMPETITIONS
K. B. Wipke, N. Hill, and R. P. Larsen Jan. 1994 13 p Presented at the Society of Automotive Engineers (SAE) Congress and Exposition, Detroit, MI, 28 Feb. - 3 Mar. 1994
(Contract DE-AC02-83CH-10093)
(DE94-000269; NREL/TP-473-6227; CONF-940242-1) Avail: CASI HC A03/MF A01

The U.S. Department of Energy sponsored several student engineering competitions in 1993 that provided useful information on electric and hybrid electric vehicles. The electrical energy usage from these competitions has been recorded with a custom-built digital meter installed in every vehicle and used under controlled conditions. When combined with other factors, such as vehicle mass, speed, distance traveled, battery type, and type of components, this information provides useful insight into the performance characteristics of electrics and hybrids. All the vehicles tested were either electric vehicles or hybrid vehicles in electric-only mode, and had an average energy economy of 7.0 km/kwh. Based on the performance of the 'ground-up' hybrid electric vehicles in the 1993 Hybrid Electric Vehicle Challenge, data revealed a 1 km/kwh energy economy benefit for every 133 kg decrease in vehicle mass. By running all the electric vehicles at a competition in Atlanta at several different constant speeds, the effects of rolling resistance and aerodynamic drag were evaluated. On average, these vehicles were 32% more energy efficient at 40 km/h than at 72 km/h. The results of the competition data analysis confirm that these engineering competitions not only provide an educational experience for the students,

but also show technology performance and improvements in electric and hybrid vehicles by setting benchmarks and revealing trends. DOE

STOCHASTIC STABILITY AND NONLINEAR CONTROL IN MECHANICAL SYSTEMS Ph.D. Thesis
Sanjiv Talwar 1993 209 p
Avail: Univ. Microfilms Order No. DA9314948

Almost-sure asymptotic stability of 3 and 4 dimensional co-dimension two dynamical systems under small intensity stochastic excitations is investigated. The method of stochastic averaging is used to derive a set of approximate Ito equations which are then examined to obtain the almost-sure stability conditions. The sample properties of the process are based on the boundary behavior of the associated scalar diffusion process of the amplitude Ito equations. This method is then applied to a linear, gyroscopic problem of a rotating shaft with a random loading demonstrating the conservative nature of mean square stability. In addition to stochastic excitations, many systems also undergo harmonic loading. The almost-sure stability of two degree-of-freedom systems subjected to both random and harmonic excitation is then investigated. In this analysis, stochastic averaging followed by a perturbation theoretic approximation is used to facilitate the solution of the multi-dimensional diffusive Markov process. The emerging field of nonlinear control theory has attempted to alleviate the problem associated with applying linear control theory to nonlinear problems. A segment of nonlinear control theory, called exact feedback linearization, has proven useful in a class of problems satisfying certain controllability and integrability constraints. Approximate feedback linearization has enlarged this class by weakening the integrability conditions, but application of both these techniques remains limited to problems in which a series of linear partial differential equations can easily be solved. By use of the idea of normal forms, from dynamical systems theory, a method of obtaining the necessary coordinate transformation and nonlinear feedback rules is given. This method, algebraic in nature, is valid for any dimensional system and any order nonlinearity provided it meets the approximate feedback linearization conditions. Dissert. Abstr.

SLIDING FRICTION AND WEAR BETWEEN TITANIUM NITRIDE, M50 STEEL AND SILICON NITRIDE (ROUND 3 OF VAMAS WEAR TEST PROGRAM)
S. K. Yick and H. M. Hawthorne Feb. 1994 42 p
(IMR-TM-TR-003; CTN-94-61134) Avail: CASI HC A03/MF A01

As a continuation of the Versailles Project on Advanced Materials and Standards (VAMAS) wear test program, a series of wear tests was conducted on common source specimens of M50 steel, TiN coating, and Si3N4. The objective of the program is to obtain reliable information on the reproducibility of test results for establishing internationally agreed-to wear test methodology. Results of the unlubricated sliding wear tests of three material pair combinations performed on a pin-on-disc tribometer using new test procedures are reported. The friction and wear behavior of each material pair is discussed in relation to the morphology of the wear debris generated on the worn specimen surfaces. The unworn TiN coatings on the disc specimens are characterized by surface profilometry and ultra micro indentation. The three material combinations are ranked, with regard to both friction and wear, in the order M50/TiN - Si3N4/TiN - TiN/TiN. Author (CISTI)

A STUDY OF THE FLEXIBLE SPACE PLATFORM BASED DEPLOYABLE MANIPULATOR Ph.D. Thesis
Itshak Marom Jul. 1993 196 p
(ISBN-0-315-85410-3; CTN-94-61156) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A relatively general formulation is presented for studying the nonlinear dynamics and control of a flexible space-based mobile deployable manipulator. The formulation is applicable to a two-link deployable manipulator translating along a flexible space platform. The manipulator's revolute and prismatic joints are flexible with finite gear ratio and rotor inertia. The nonlinear nonautonomous and coupled equations of motion are presented in compact form, and validity of the formulation and computer code were established through checks on conservation of system energy and comparison with test cases. Results of the dynamical analysis clearly show that under critical combinations of parameters, the system can become unstable. An inverse kinematic technique, accounting for the linear and angular displacements of the flexible platform, has been developed to meet the desired position and orientation requirement of the end effector with respect to the chosen reference frame. A nonlinear control strategy based on the feedback linearization technique was developed to ensure accurate tracking of a desired trajectory in presence of system libration as well as the base translations and vibrations. Closed loop simulation results show that a desired degree of system stability and high tracking accuracy can be achieved. Author (CISTI)

TERNARY ARC GAS PLASMA WELDING TORCH Patent Application
Daniel J. Rybicki, inventor (to NASA) (Martin Marietta Corp., Huntsville, AL.), William F. McGee, inventor (to NASA) (Martin Marietta Corp., Huntsville, AL.), and Douglas J. Waldron, inventor (to NASA) (Waldron, Douglas J..) 27 Dec. 1993 12 p
(NASA-Case-MFS-28857-1; NAS 1.71:MFS-28857-1; US-Patent-Appl-SN-172961) Avail: CASI HC A03/MF A01

A plasma arc welding torch wherein a first plasma gas is directed through the body of the welding torch and out of the body across the tip of a welding electrode disposed at the forward end of the body. A second plasma gas is disposed for flow through a longitudinal bore in the electrode. The second plasma gas enters one end of the electrode and exits the electrode at the tip thereof for co-acting with the electric welding arc to produce the desired weld. A shield gas is directed through the torch body for circulating around the head of the torch adjacent to the electrode tip. NASA

GENERATION OF GEAR TOOTH SURFACES BY APPLICATION OF CNC MACHINES Final Report
F. L. Litvin and N. X. Chen Apr. 1994 84 p
(Grant NAG3-1263; DA Proj. 1L1-62211-A-47-A; RTOP 505-62-36)
(NASA-CR-195306; E-8712; NAS 1.26:195306; ARL-CR-145) Avail: CASI HC A05/MF A01

This study will demonstrate the importance of application of computer numerically controlled (CNC) machines in generation of gear tooth surfaces with new topology. This topology decreases gear vibration and will extend the gear capacity and service life. A preliminary investigation by a tooth contact analysis (TCA) program has shown that gear tooth surfaces in line contact (for instance, involute helical gears with parallel axes, worm gear drives with cylindrical worms, etc.) are very sensitive to angular errors of misalignment that cause edge contact and an unfavorable shape of transmission errors and vibration. The new topology of gear tooth surfaces is based on the localization of bearing contact, and the synthesis of a predesigned parabolic function of transmission errors that is able to absorb a piecewise linear function of transmission errors caused by gear misalignment. The report will describe the following topics: description of kinematics of CNC machines with six degrees of freedom that can be applied for generation of gear tooth surfaces with new topology. A new method for grinding of gear tooth surfaces by a cone surface or surface of revolution based on application of CNC machines is described. This method provides an optimal approximation of the ground surface to the given one. This method is especially beneficial when undeveloped ruled surfaces are to be ground. Execution of motions of the CNC machine is also described. The solution to this problem can be applied as well for the transfer of machine tool settings from a conventional generator to the CNC machine. The developed theory required the derivation of a modified equation of meshing based on application of the concept of space curves, space curves represented on surfaces, geodesic curvature, surface torsion, etc. Condensed information on these topics of differential geometry is provided as well. SURFACE FATIGUE LIFE OF HIGH TEMPERATURE GEAR MATERIALS
Dennis P. Townsend Apr. 1994 12 p Proposed for presentation at

the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; sponsored by AIAA, ASME, SAE, and ASEE
(DA Proj. 1L1-62211-A-47-A; RTOP 505-62-36)
(NASA-TM-106562; E-8738; NAS 1.15:106562; ARL-TR-401; AIAA Paper 94-3078) Avail: CASI HC A03/MF A01

Three high temperature gear materials were evaluated using spur gear surface fatigue tests. These materials were, VASCO max 350, VASCO matrix 2, and nitralloy N and were evaluated for possible use in high temperature gear applications. The fatigue life of the three high temperature gear materials were compared with the life of the standard AISI 9310 aircraft gear material. Surface fatigue tests were conducted at a lubricant inlet temperature of 321 K (120 F), a lubricant outlet temperature of 350 K (170 F), a maximum Hertz stress of 1.71 GPa (248 ksi), a speed of 10,000 rpm, and with a synthetic paraffinic lubricant. The life of the nitralloy N was approximately the same as the AISI 9310, the life of the VASCO max 350 was much less than the AISI 9310 while the life of the VASCO matrix 2 was several times the life of the AISI 9310. The VASCO max 350 also showed very low fracture toughness with approximately half of the gears failed by tooth fracture through the fatigue spall. The VASCO matrix 2 had approximately 10-percent fracture failure through the fatigue spalls indicating moderate to good fracture toughness. Author (revised)

NUMERICAL PREDICTION OF MIXING PROCESS IN A METHANE-FUELED ENGINE Ph.D. Thesis
Mehmet Emin Arici 1993 179 p
Avail: Univ. Microfilms Order No. DA9325771

One of the most important factors controlling the combustion process within internal combustion engines is the charge mixing. The charge mixing process in a gaseous fueled engine is different than that in a liquid fueled engine. In a conventional liquid fueled engine, the liquid fuel goes through the process of vaporization before the gaseous mixing takes place. Gaseous fuels, on the other hand, are already in a vapor form and do not go through the vaporization process. Among the gaseous fuels, natural gas, which consists of about 90 percent methane, is gaining acceptance because of its low emission levels and alternative energy source concerns. Introducing methane into the conventional spark ignition engine intake system causes about a 10 percent engine power loss contributed by low density of the fuel. By introducing natural gas directly into the engine cylinder, this power loss can be reduced. The present work concerns numerical prediction of in-cylinder methane/air mixing preparation. A computer-based solution procedure, which employs a finite difference solution of general conservation equations of motion in a piston/cylinder assembly, has been developed to predict the fuel/air mixing characteristics. This solution procedure has been used as a predictive tool to investigate the dependence of charge mixing characteristics on the flow field in the absence of combustion. Computational results show that the flow field has a great effect on charge mixing. The fuel/air mixing characteristics at the time of initiation of combustion are satisfactorily close to the mixing requirements when the fuel charging is prescribed properly. Dissert. Abstr.

EXPERIMENTAL SLIDING MODE CONTROL OF A FLEXIBLE SINGLE LINK MANIPULATOR Ph.D. Thesis
Timothy Wei Tie Qian Sep. 1993 215 p
(ISBN-0-315-85466-9; CTN-94-61161) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A study was conducted to explore and develop practical controller designs for a flexible manipulator based on the variable structure (VS) system and sliding mode (SM) theory. A new control design method is first proposed based on the continuous time VSSM theory, which can significantly simplify the VS system design process. Moreover, the variables concerned can be assigned separate gains. Direct application of the VSSM control system to the flexible arm, however, has limitations due to the inherent properties of the system. To solve this problem, facilitate digital implementation, and eliminate undesirable chattering in conventional VS system control, the discrete time quasi sliding mode control (DQSMC) is developed. Two control algorithms are derived satisfying the conditions for existence of discrete time sliding hypersurfaces. It is proven that the DQSMC design is equivalent to a full state feedback with its steady state motion constrained to the sliding hypersurfaces, and that DQSMC provides a general structure unifying the three different kinds of discrete time SM control. Experimental testing of the DQSMC controller showed good results, which compared favorably to the linear quadratic Gaussian controller under the same load variations. A novel approach was then devised to realize the proposed new controller designs. Author (CISTI)

TECHNICAL ANALYSIS OF ALTERNATIVE FUELED VEHICLES
Mar. 1993 10 p
(DE94-744238; ETDE/JP-MF-94744238) Avail: CASI HC A02/MF A01

The current status of alternative fueled vehicles, such as methanol fueled, compressed natural gas (CNG) fueled, and electric vehicles, that have feasibility to take the place of oil fueled ones is analyzed from the viewpoints of environmental pollution control, energy resources conservation, and economic performances. As for environmental pollution control, these three vehicles are compared by such items as nitrogen oxides, photochemical reactivity, adaptability to future regulations, earth warming substances, and toxicity. As for practical applicability, the following items are compared: power density (torque, power, acceleration performance), energy density, range, energy consumption, vehicle initial costs, energy costs, freight transportation energy costs (yen/ton/km), and energy supply suitability. Conclusions include: methanol vehicles have the problem of fueling stations to be arranged; since CNG vehicles are considered to be loaded with CNG fuel tanks on the top of vehicles, safety must be ensured; electric vehicles still have many problems in spite of their many advantages. PROCEEDINGS OF THE 3RD CONFERENCE ON MILITARY ROBOTIC APPLICATIONS
David J. Mackay, ed. 1991 349 p Conference held in Medicine Hat, Alberta, 9-12 Sep. 1991 Prepared in cooperation with Alberta Research Council, Edmonton
(DRES-SP-149; CTN-94-61130) Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A conference on military robotics focused on developments in intelligent robotic systems for military applications and on advances in component technologies. The objective of the conference was to provide a forum for representatives from government, industry, and universities to meet and discuss advances in the field of intelligent robotic systems. Papers were presented on battlefield robotics, guidance and navigation, robotic arm control, robotic sensing, supervisory control, and unmanned vehicles. Separate abstracts have been prepared for 37 papers from this conference. For individual titles, see N94-30276 through N94-30312.

AUTONOMOUS INTELLIGENT MILITARY ROBOTS: ARMY ANTS, KILLER BEES, AND CYBERNETIC SOLDIERS
Robert Finkelstein *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 4-11 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The rationale for developing autonomous intelligent robots in the military is to render conventional warfare systems ineffective and indefensible. The Desert Storm operation demonstrated the effectiveness of such systems as unmanned air and ground vehicles and indicated the future possibilities of robotic technology. Robotic military vehicles would have the advantages of expendability, low cost, lower complexity compared to manned systems, survivability, maneuverability, and a capability to share in instantaneous communication and distributed processing of combat information. Basic characteristics of intelligent systems and hierarchical control systems with sensor inputs are described. Genetic algorithms are seen as a means of achieving appropriate levels of intelligence in a robotic system. Potential impacts of robotic technology in the military are outlined. Author (CISTI)

ROBOTICS AND THE BATTLEFIELD OF THE FUTURE

Erik Solem *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 19-25 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The possible future roles for robotics are discussed from a military and strategic point of view. The future battlefield itself is then examined along with some of the anticipated changes which may take place. Robotics is likely to play a major role in future military operations. Robotic equipment will be increasingly used on the battlefield, aboard ships, on land, in the air, and in space applications. Potential application areas extend beyond such important operations as minefield clearing, reconnaissance, ammunition handling, and construction tasks. The future battlefield itself will change with the introduction of new forms and factors of combat. There will be qualitatively different forms of conflict in which robotics may play specific and important roles, such as masked clashes, anti-terrorist activities, and anti-industrial sabotage operations. The battlefield itself will widen and include new strategic factors of increasing importance. Our understanding and use of robotics will also change. Nonconventional strategies are needed as are new and different conflict scenarios, some of which are examined.

DREV ACTIVITIES RELATED TO MILITARY VEHICLES ROBOTIZATION
B. Montminy *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 37-41 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The Defence Research Establishment Valcartier (DREV) is involved in a number of activities aimed at improving the performance of systems installed aboard military vehicles, automating functions normally carried out by human operators, and adding new functions that become essential to cope with new scenarios and threats. These activities relate to the development of sensors that sense the surrounding environment, processors that interpret the sensor data, and actuators that perform various robotic actions. DREV research related to those activities is reviewed as they relate to robotics which continues to increase the portion of vehicular function that is carried out autonomously. Of special interest is the CF aircraft robotization project which aims to develop an autonomous integrated aircraft protection system to detect and counter threats without any human intervention. This research involves development of means for passive surveillance of the surrounding environment, processing of multisensor data, triggering of sensing-aid devices, and actuation of countermeasures that modify the environment.

AUTONOMOUS ROBOTIC REFUELING SYSTEM (ARRS) FOR RAPID AIRCRAFT TURNAROUND
O. R. Williams, E. Jackson, K. Rueb, B. Thompson, and K. Powell *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 42-46 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An autonomous robotic refuelling system is being developed to achieve rapid aircraft turnaround, notably during combat operations. The proposed system includes a gantry positioner with sufficient reach to position a robotic arm that performs the refuelling tasks; a six degree of freedom manipulator equipped with a remote center of compliance, torque sensor, and a gripper that can handle standard tools; a computer vision system to locate and guide the refuelling nozzle, inspect the nozzle, and avoid collisions; and an operator interface with video and graphics display. The control system software will include components designed for trajectory planning and generation, collision detection, sensor interfacing, sensory processing, and human interfacing. The robotic system will be designed so that upgrading to perform additional tasks will be relatively straightforward.

THE NRC MOBILE ROBOT PROJECT
Ramiro Liscano, David Green, Allan Manz, Larry Korba, and Sherman Lang *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 47-53 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An overview is presented of the autonomous mobile robot project being conducted at the National Research Council of Canada. The main area of investigation is autonomous navigation of a vehicle in an indoor environment. A brief outline is given of a line-of-sight path planning algorithm which uses line representations of data from a laser range scanner to compute a collision-free path through a cluttered environment. This is followed by a description of a reflexive collision avoidance algorithm based on a histogram representation of ultrasound sensor data extracted from a certainty grid. Implementation details of these two collision avoidance methods on an autonomous platform is also described. The research is aimed at eventually designing a system to navigate in an indoor environment autonomously and to be robust enough to do this reliably.

EXTENDED OCCUPANCY GRID METHOD FOR MODELLING UNKNOWN DYNAMIC ENVIRONMENTS **c04**
Robert E. Webber and Yue-Feng Zhang *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 54-60 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The occupancy grid method represents a region to be navigated as a grid of cells. Within each cell, there is an associated probability that the cell is occupied given a robot's knowledge coming from sensor readings. The behavior of the sensors is modelled conceptually by an array of probabilities. A Bayesian updating procedure allows each sensor reading to be combined with existing knowledge to produce a new worldview. Path planning can then be performed directly on the grid information without additional scene analysis processing. The occupancy grid method was developed for handling a world where the robot was the only moving object, thus it lacks the ability to predict the location of a moving obstacle at some future time. An approach has been developed for extending the method to handle obstacles moving at constant velocity. The two dimensional grid representation is extended to be a four dimensional representation of location and velocity combinations. Each grid cell stores the probability that there is not an obstacle at time t at location x,y moving with velocity Vx,Vy. Experiments with a number of rules for combining the sensor information with grid values to produce new grid values are reported and evaluated.

NAVIGATION OF MILITARY AND SPACE UNMANNED GROUND VEHICLES IN UNSTRUCTURED TERRAINS **c04**
Paul Lescoe (Army Tank-Automotive Command, Warren, MI.), David Lavery, and Roger Bedard *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 61-67 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Development of unmanned vehicles for local navigation in terrains unstructured by humans is reviewed. Modes of navigation include teleoperation or remote control, computer assisted remote driving (CARD), and semiautonomous navigation (SAN). A first implementation of a CARD system was successfully tested using the Robotic Technology Test Vehicle developed by Jet Propulsion Laboratory. Stereo pictures were transmitted to a remotely located human operator, who performed the sensing, perception, and planning functions of navigation. A computer provided range and angle measurements and the path plan was transmitted to the vehicle which autonomously executed the path. This implementation is to be enhanced by providing passive stereo vision and a reflex control system for autonomously stopping the vehicle if blocked by an obstacle. SAN

achievements include implementation of a navigation testbed on a six wheel, three-body articulated rover vehicle, development of SAN algorithms and code, integration of SAN software onto the vehicle, and a successful feasibility demonstration that represents a step forward towards the technology required for long-range exploration of the lunar or Martian surface. The vehicle includes a passive stereo vision system with real-time area-based stereo image correlation, a terrain matcher, a path planner, and a path execution planner. Author (CISTI)

A GENERIC SEMI-AUTONOMOUS GROUND VEHICLE CONTROL SYSTEM **c63**
Ron Eirich and Alan Kramer *In its* Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 68-73 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A generic control system has been developed which is capable of piloting virtually any surface vehicle and navigating semi autonomously to deliver a payload. The system permits an incremental approach to autonomy, since software and hardware modules can be easily added as developments occur. The modular nature of the system also enables quick repair and allows it to be easily installed on any ground vehicle just by redesigning a personality module for that vehicle. The first phases of development involved extensive system definition and construction of hardware to enable tele-operated control. The second phase added semiautonomous operation utilizing global positioning system information. Subsequent phases will add obstacle detection and avoidance, multiple vehicle control, and route planning. Field trials have shown the system to operate reliably over long distances. The system's vehicle electronics package and control station are described and some operational roles in both military and civilian applications are outlined. Author (CISTI)

ENCODING TECHNIQUE FOR AUTOMATED GUIDED VEHICLE POSE RECOVERY IN A STRUCTURED ENVIRONMENT **c04**
E. Petriu, T. Bieseman, N. Trif, W. S. McMath, and S. K. Yeung *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 86-92 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A new position orientation and scaling estimation (POSE) recovery method is presented for a free-ranging automated guided vehicle (AGV) moving in an encoded environment using vision. The environment is structured by permanently encoding the floor with the terms, marked by distinct graphical symbols, of a pseudo random binary array (PBRA) requiring only one bit of code per quantization interval, independent of the desired resolution. The PRBA-based two-dimensional encoding method is discussed and results of its application in an experimental AGV for absolute position recovery are described. The proposed PRBA-based POSE recovery technique is restricted in applicability to controllable environments such as nuclear plants and space stations which allow for object encoding and a-priori mapping of all encoded surfaces in a geometric data base. The experiments validated the performance and practical value of the encoding method presented. Author (CISTI)

AN OPTIMAL OBSTACLE AVOIDANCE PATH PLANNING ALGORITHM FOR THE EXCALIBUR ROBOT **c63**
V. Banerjee, C. Earl, T. D. Looke, and M. Farooq *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 93-98 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An algorithm was developed using a heuristic approach to solve the problem of obstacle avoidance of a robot arm and payload moving among cylindrical obstacles. The algorithm is optimized with respect to minimum distance and minimum joint rotation criteria. The strategy was implemented and tested on a laboratory Excalibur robot using Automatix's RAIL programming language on a Macintosh IIx. The algorithm is described in its six steps: obstacle identification, obstacle prioritization, feasible path set creation, optimal path selection, optimal path execution, and position update. The algorithm is iterative; once all the obstacles have been identified and prioritized, the last four steps of the algorithm are accomplished for each obstacle separately in order of priority. A more in-depth strategy is provided for critical situations when an object is in the line of sight between the base coordinate system and the desired manipulator position, or when each of the avoidance paths is found to be non-feasible. The path planning obstacle avoiding algorithm is a simple and effective solution to the problem of moving the Excalibur robot arm in a restricted workspace. Author (CISTI)

MAESTRO: AN OPEN SYSTEM ARCHITECTURE FOR MULTI-ROBOT CONTROL **c63**
Shadia Elgazzar and Arthur Castonguay *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 99-106 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Replacing the robot controller supplied by the manufacturer with a multiprocessor system based on an industry standard microcomputer system bus and an object based software architecture results in a flexible open system architecture for single/multiple robot control. This architecture allows the integration of sensors and other peripherals in an effective and simple way, and is able to meet the realtime requirements of the system. The controller has been named Maestro to complement Harmony, the name of the operating system, and to convey the idea of conducting multiple robots. The hardware implementation and software functionality of Maestro is presented along with the available robot system environments and robot programming levels. The task structure for Maestro and the method used for communication and synchronization are also detailed. An object-oriented software design has allowed extraction of inherent parallelism in the controller, which was then exploited using the available hardware architecture and operating system. COORDINATED CONTROL OF MULTIPLE ROBOT MANIPULATORS
S. Kalaycioglu and D. S. Necsulescu *In* Defence Research Establishment

Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 107-113 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The coordination of multiple robots is achieved by the control of each arm in a nonconflicting way as the robots control the position of an object being handled. An analysis of the load distribution problems for coordinating robots handling a single payload is carried out and an optimal load sharing algorithm is applied to a possible task. The minimum (norm) joint torques and minimum contact forces are obtained by the minimization of a quadratic function associated with the joint torques and the force vectors of multiple robot arms with the constraints of the robot system equations. The applied algorithm is not computationally intensive compared with existing algorithms described in the literature and is therefore very attractive for real-time applications. The effectiveness of the control strategy for coordinated motion of the robots performing different tasks is checked by digital simulation. It is noted that the control strategy is very effective and the investigated control architecture is well suited for a distributed computer architecture. Author (CISTI)

THREE METHODS TO IMPROVE THE ACCURACY OF A PUMA 560 ROBOT **c63**
G. R. Hardy *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 114-121 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

It is planned to use the PUMA 560 six-axis robotic arm to scan surface areas of CF-18 aircraft with an ultrasonic scanner to detect delaminations in composite materials. A problem with using a robot to perform repeatable scans on a CF-18 is accuracy. Although the calibration method is accurate enough at the present time, it is complex to implement and requires a very fast computer to correct errors in realtime. Three simple methods to improve scanning accuracy are compared. One method uses an ultrasonic positioning system to continuously correct position. The second uses the positioning system to correct only the endpoints of the scan lines. The third method, a modified calibration technique, corrects six of the 24 parameters defining the manipulator. Both methods using the positioning system reduce errors to an acceptable level as long as there is a clear line of sight between the transmitter mounted on the arm and the receivers. However, large errors occur when a direct path is blocked and the system responds to a reflected signal. The third method is robust and reliable, but not as accurate as the other two. Author (CISTI)

FORCE CONTROL TECHNIQUES FOR ROBOT MANIPULATORS AND THEIR MILITARY APPLICATIONS
P. Wojcik and K. Chrystall *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 122-128 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An overview is presented of existing techniques for providing compliant motion control to robot manipulators. Active compliance of robot manipulators can be achieved by using either logic branching feedback or continuous feedback methods, but the latter has a broader range of potential applications. The theoretical background, working principles, and advantages and drawbacks of two continuous feedback approaches are discussed. These approaches are hybrid position/force control, which integrates explicit force control and pure position control concepts, and impedance control, in which a specific mechanical impedance is achieved at the manipulator end-effector. The requirements of compliant motion control (force control) for military robotics are outlined and three scenarios of force control applications are presented: ordnance handling, refuelling of vehicles, and mine field clearing. AN INVERSE KINEMATICS ALGORITHM FOR THE DREP/PHILIPS REAL-TIME RADIOGRAPHIC MANIPULATOR SYSTEM **c63**
K. K. Yeung *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 129-135 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A gantry-type robotic manipulator was installed in a real-time radiography research facility to develop automated radiographic inspection procedures for large-area aircraft structures. The original position controller of the manipulator system is a set of three joysticks designed only for manual operations. Numerical control capability has been added to allow direct control of the scanning motion from an external computer. In order to move the radiographic imaging end-effector to a given location in the world coordinate system, an inverse algorithm is required to compute the joint variables for the desired end-effector location. A closed-form inverse kinematics algorithm is presented for the manipulator system. The algorithm was implemented in a C language program. Robot modelling and simulation techniques were used to facilitate the development and verify the functionality of the program. Using the CIMSTATION robot simulation software, it was possible to simulate the inspection operation performed by the manipulator on a disassembled leading edge flap of the CF-18 aircraft. HATT-X: A HIGH PERFORMANCE FLYING LABORATORY FOR AUTONOMOUS UNMANNED AIRCRAFT RESEARCH AND DEVELOPMENT **c05**
Alex B. Markov and Robert W. Herring *In its* Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 136-142 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An experimental flight vehicle has been developed by the Canadian Forces to serve as a flying platform on which to investigate and demonstrate a variety of emerging technologies. This vehicle is the High-speed Aeronautical Technologies Testbed (HATT-X), a high subsonic speed rocket powered drone that has evolved from the ROBOT-X aerial target drone. HATT-X is a highly maneuverable platform that is capable of autonomous and semiautonomous flight. It is currently being used to investigate a number of drone technologies. Capabilities that are being pursued include highly agile evasive maneuvering, the ability to take intelligent actions to counter defensive measures, and supersonic flight. Current capabilities of HATT-X and ongoing research and development are reviewed. Planned enhancements that will facilitate a number of advanced configurations are also discussed. Author (CISTI)

SIMULATION OF LIGHTWEIGHT ROBOTS AND THEIR CONTROLLERS
J.-C. Piedboeuf and R. J. Ferguson *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 143-149 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The development of a simulator for a n-degree of freedom robot with elastic joints and flexible links is described. The model of the robot is derived using d'Alembert's principle and takes into account both the stiffening effect and the angular momentum of the rotors in the robot motors. A closed kinematic loop is allowed for between the endpoint of the manipulator and the working plane. These kinematic loops are handled using Lagrange multipliers. A general formulation for the Jacobian derivative for any rigid or flexible robot was also developed and implemented. The control problem is discussed for flexible robots, in which the endpoint and not the joint has to be controlled. The suite of programs used for developing the simulator has modules for model generation, model simulation, and system analysis. The first two modules are written in Fortran while the core of the third is the MATLAB commercial software package. Author (CISTI)

THE RESPONSE OF FLEXIBLE MANIPULATORS TO A NEW COMPUTED TORQUE CONTROL STRATEGY: SIMULATION RESULTS
T. D. Looke, M. M. Bayoumi, and M. Farooq *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 150-156 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The need for faster and lighter autonomous and teleoperated robots, especially in military land, undersea, and space applications, requires control algorithms which account for the elastic response of lightweight, flexible structures. The numerical analysis and testing of these control algorithms further requires accurate simulation techniques. The finite element simulation method generally yields very accurate predictions of the transient dynamic response of flexible structures to applied loads. It is shown that a standard finite element simulation package (ANSYS) may be used to test computed torque and adaptive feedback control algorithms for multi-link flexible manipulators. The response of one- and two-link, planar and non-planar flexible manipulators to computed torque algorithms is illustrated. The results demonstrate the usefulness of the new computed torque approach.

SYMBOLIC GENERATION OF DYNAMICS EQUATIONS FOR MANIPULATORS MOUNTED ON MOVING BASES **c63**
R. W. Toogood, L. El-Rayyes, and D. J. Mackay *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 157-164 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

With the growing interest in lightweight and high-speed robots, the effects of link flexibility have been included in dynamic models of robots. Generally, such models concern robots mounted on a fixed base and under the influence of gravity. This is not the case, however, with robots mounted on space vehicles, on moving earthbound vehicles, or for small manipulators mounted on the end of a larger robot arm. A number of programs have therefore been implemented for the symbolic generation of computer code for the inverse and direct dynamic analysis of serial link robots mounted on moving bases. A review of these programs is presented, including the implemented dynamics algorithms, the major features of the symbolic generation procedures, and the computational efficiency of the generated code. The added computational load from including the base motion is shown. Some dynamics simulation results are described for a three link rigid manipulator mounted on an oscillating base, which graphically illustrates the effect of the base movement on the manipulator dynamics.

ACTIVITIES IN MACHINE VISION AT IMAGO MANUFACTURING LTD. **c63**
Roy Ball, Terry Folinsbee, and Lionel Pelkowitz *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 165-168 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

An overview is presented of machine vision research and development at Imago in the areas of robotic control, target tracking, image stabilization, and image registration. Applications are aimed at real-world scenarios which present the machine vision system with various combinations of low contrast, noise, variable illumination, cluttered background, and partial obscuration of the objects of interest. A powerful near-realtime software development system has been built featuring a wide range of algorithms and a software architecture that quickly determines the best combinations of algorithms for a given application. The software is designed for easy migration to more powerful and/or cost-effective platforms as necessary.

VARIABLE-RESOLUTION STEREO MATCHING **c63**
Anup Basu *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 169-176 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The human visual system can be characterized as a variable resolution system. Foveal information is processed at very high spatial resolution while peripheral information is processed at low spatial resolution. Although the quantitative aspects of this variable resolution processing are known quite precisely, it is unclear what computational advantages it has over uniform resolution processing. It is demonstrated that variable resolution visual processing can indeed be useful in stereo matching and vergence control. A method is presented for controlling vergence movements using a variable resolution representation of the input image. The method relies on a very simple scheme for matching edges of the left and right views, ignoring any constraints that might be used for eliminating false edge alignments. It is shown that this approach generates a matching function, with disparity as a free variable, which increases to a peak corresponding to the correct match and then decreases. The shape of the matching function helps in obtaining rapid and reliably correct vergence with respect to a given object.

MOTION AND STRUCTURE FROM PLANAR MOTION IN NOISY MONOCULAR IMAGE SEQUENCES **c74**
V. C. Aitken and H. M. Schwartz *In its* Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 177-184 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Linear motion and structural models are proposed for a rigid object which is constrained to lie on a known planar surface, and a nonlinear measurement model which describes noisy monocular perspective projection observations from an arbitrary position above the known plane. Absolute motion and structural parameters are recovered with discrete time extended Kalman filtering in the presence of feature point occlusion. Comparison of Monte Carlo simulation results with approximate Cramer-Rao bounds demonstrates algorithm performance. In the planar motion problem, all feature points lie at constant heights relative to the plane of motion. A fundamental assumption of the proposed technique is that the height of one feature point from the plane is known or approximated. Another limitation is that the systems as formulated are not observable for zero angular velocity. Filter performance can be seriously degraded as rotational rates become very small.

THERMAL IMAGING FOR A MOBILE ROBOT **c74**
Claude Caillas *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 191-197 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A novel model is presented that uses thermal imaging for identifying different types of materials in outdoor scenes. The thermal imaging model is described, showing that it is possible to calculate body temperatures as a function of time and thermal inertia. From the model and from experiments measuring temperature of sand and rock, it is shown that the thermal inertia can be derived as a function of temperature and time. This should allow determination of the type of material, since thermal inertia is a characteristic of materials. The application envisaged for this materials identification technique is exploration of the surface of Mars using an autonomous robot. The infrared sensing requirements for Mars are summarized and the problems of determining grain size of the material, choosing footfall positions for the robot, and selecting sites for material collection are described. The thermal imaging technique is thought to be able to distinguish between dust, sand, and rock, allowing the robot to infer soil features such as load-bearing capacity and coefficient of friction.

Distinguishing between varieties of sand is theoretically possible.

SONAR SENSING AND OBSTABLE DETECTION **c63**
Gregory Dudek, Michael Jenkin, Evangelos Milios, and David Wilkes *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 198-205 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The problems of sensor error modeling and the exploration of unknown environments are considered in the context of mapping an unknown closed environment with a sonar sensor. The sensor characteristics are modeled, unavoidable anomalies in the data obtained are taken into account, and a long-term representation of the environment is constructed. Algorithms are presented for extracting obstacle contours from sonar data. The model of sonar range sensing for robot navigation accounts for multiple reflections of the sonar signal between transmission and reception. This controlled data acquisition methodology can be subsequently used to compare techniques for the interpretation of the acquired data. From this model of sonar sensing itself, a new model for inferring coherent reflecting surfaces is developed, based on an assumption of coherent smooth surfaces in the world. This is accomplished by using an energy based minimization algorithm to reject sonar measurements that are not consistent with an a-priori world model. Finally, a representation for large-scale structure of the environment is discussed which is based only on the topological interrelation between places of interest and the paths crossing them. OBSTACLE DETECTION FOR AN AUTONOMOUS VEHICLE **c63**
R. Neil Braithwaite and M. P. Beddoes *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 206-213 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The most primitive module in a navigational control system of an autonomous vehicle is discussed. The task performed by this module is the detection of moving and stationary obstacles from a vehicle undergoing predominantly rectilinear motion. Stereo cameras provide image flow and depth estimates from which properties of the obstacles and vehicle are extracted. Localized changes in the depth and image flow fields provide information on the position and velocity of the obstacles. Global changes in the image flow fields provide the translational and rotational velocity of the vehicle. The vehicle rotation is required to stabilize the stereo image sequence so that obstacle and vehicle motion can be estimated using pure translation Kalman filters. Important obstacle parameters, such as how close the vehicle will be as it passes the obstacle and how long before it passes, are predicted using the estimated vehicle and obstacle motions. The basis of this method is the Gabor filter whose phase response is used to extract normal image velocity and depth from the stereo image sequence. Simple experiments illustrate the potential of this method for detecting obstacles. Author (CISTI)

ELEMENTS OF SUPERVISORY CONTROL FOR MILITARY ROBOTIC APPLICATIONS **c63**
A. Dagnino, P. Feighan, and K. Chrystall *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 214-219 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Supervisory control for robots can be viewed as a spectrum ranging from teleoperated devices on one extreme to fully autonomous systems on the other. At any point along this spectrum, there is a shared responsibility of control between the human operator and the robotic device. The basic elements needed to attain a significant degree of supervisory control beyond teleoperation are reviewed. Sensor systems allow the robot's operational status and its working environment to be perceived both by the robot and the human operator. Actuator systems allow the robot to move and bring about changes in its environment. Workspace models are computer representations of the robotic system and its immediate environment, and are used to provide the information required by the machine-based planning element to generate sequences of robot activities. The machine-based planning system must be designed for a dynamic environment, reasoning with uncertainty, an ability to trace its line of reasoning, knowledge representation, and user interfacing. A supervisory control architecture, such as the NASREM hierarchical architecture, provides the means of integrating these elements into a coherent system. The application of supervisory control to military use such as aircraft refueling is discussed and future areas of research are recommended. Author (CISTI)

ASPECTS OF THE OPERATOR INTERFACE FOR MILITARY ROBOTIC APPLICATIONS IN UNSTRUCTURED ENVIRONMENTS **c54**
P. Feighan, P. Wojcik, and K. Chrystall *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 220-226 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The major challenges facing a designer of a military robotics operator interface are discussed. These include operating in unstructured environments, coping with restricted communications between operator and remote robotic system, defining the level of autonomy of the robotic system, and monitoring system health. Currently available operator interface technologies for remote robotic systems are reviewed which have been developed and tested in industrial or research laboratories. This overview includes discussion of the level of autonomy of telerobotic systems and its impact on the operator interface design, as well as description of the best ways of displaying information from the remote system and of inputting necessary commands and controls for telerobots. The concepts of military robotics operator interfaces are then introduced, based on two scenarios: simple teleoperation and remote control of a semiautonomous robotic system. Both use synthetic graphics to help the operator understand the work environment. This technology has recently been found very useful and its importance in operating remote robotic systems is expanding. Further areas of research are recommended. Author (CISTI)

SUPERVISED AUTONOMOUS CONTROL FOR SPACE STATION SPECIAL PURPOSE DEXTROUS MANIPULATOR (SPDM) ROBOT
Guy Immega *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 227-232 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The Special Purpose Dextrous Manipulator (SPDM) robot is intended to be built as part of Canada's contribution to Space Station Freedom. The SPDM will help to reduce astronaut workload and instead of providing closer coupling of the operator to the robot through telepresence, the robot control system will be upgraded with the ability to function autonomously under operator supervision. For supervised autonomous operation of the SPDM to be successful, new technologies must be integrated into a system design to accommodate the task requirements, the inherent limitations of the SPDM manipulators, and the demands made on the human operators. Innovative technologies are being developed for the SPDM project, and are reviewed in the areas of system conceptual design, operator interface, task planning and execution, database design, modeling of the SPDM configuration and the immediate work region, and vision system processing. A TESTBED FOR THE DEVELOPMENT OF GROUND-BASED CONTROL OF SPACE-BASED MANIPULATORS
E. Jackson, K. Buchan, D. Eddy, G. Springle, K. Chrystall, P. Feighan, and A. Dagnino *In* Defence Research Establishment Suffield, Proceedings of

the 3rd Conference on Military Robotic Applications 1991 p 233-241 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

A project is under way to develop ground-based control technologies for space-based robots. This is a critical step in the development of autonomous control capabilities for space-based robots such as on the Space Station Freedom. Fundamental requirements for autonomous control are described in the areas of inputs and outputs, planning capability, workspace modeling, impedance control, and goal seeking behavior. To understand the tasks that the space based robot is to perform, hardware simulation of the work tasks must be performed. This requires a hardware simulation facility to allow testing of proposed robotic work task scenarios. Such a facility is being designed in the form of a testbed that will include components to emulate both ground and space based equipment, including the robotic manipulator. The integrated testbed system is reviewed, including the operator interface, planning system, manipulator control coordinator, workspace modeling computer, low level control system, vision system, and testbed manipulator. ACHIEVING ROBOT AUTONOMY **c63**
Eric Jackson, Owen Williams, and Keir Buchan *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 242-248 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Autonomy is defined as a measure of supervision and is quantified in terms of communication bandwidth. The need for increased autonomy is established and the driving and opposing factors are identified. The close relationship between increased autonomy and reduced bandwidth of a robot control channel and its data channel is established. The command channel bandwidth can be reduced by decreasing the performance requirements in the work task and by offloading the high frequency, high resolution, and high degree of freedom tasks to the robot. Reduction of the data channel bandwidth may be achieved by adding the appropriate data processing capabilities to the robot, by adding actuators or effectors to allow the robot to act on the data, by increasing the capability of the robot to handle complexity, and by reducing the risk of the robot acting on the data. Increases in robot autonomy result in increases in their responsibility to interpret their environment and act as desired. Health monitoring and fault tolerance become significant issues. Finally, several requirements for autonomous robotic control systems are presented. Author (CISTI)

IMPROVING THE EXECUTION SPEED OF ROBOT CONTROL COMPUTATIONS: AN ALLOCATION SCHEME FOR HETEROGENEOUS MULTIPROCESSORS **c63**
M. McKay, M. Farooq, and C. Wortley *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 249-254 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

As the environment in which a robot operates and the autonomy of its operation increases in complexity, the computers used to control the robot often become inadequate. If a multiprocessor is used as a controller, affordable increases in processing power can be made one board at a time. The resulting heterogeneous multiprocessor requires special task allocation routines to ensure optimum utilization and minimum real-time delay. A method is proposed for heterogeneous multiprocessor pre-runtime task allocation which attempts to minimize the execution time of an acyclic sequence of tasks with precedence constraints on a given heterogeneous multiprocessor. The multiprocessor is assumed to be tightly coupled with shared memory. The method involves a branch and bound heuristic search which finds a good initial solution to the allocation problem and then tries to improve the solution through exhaustive search. Author (CISTI)

MOTION CONTROL OF MOBILE ROBOTS **c63**
D. S. Necsulescu and S. Kalaycloglu *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 255-260 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

For most military applications, or for dealing with unstructured tasks in unstructured or uncertain environments, controllers for mobile robots and automatic guided vehicles require a suitable robot model in order to interact with the environment as well as to perform a collision-free motion incorporating sensory information about the environment. The artificial impedance approach is used for developing the high level controller of a mobile robot. The kinematic and dynamic models of a three-wheel mobile robot are first described. The control of the mobile robot is formulated so that the robot behaves like a linear virtual impedance linking the center of mass of the mobile robot and the destination point. Simulation results for obstacle-free work volumes are presented. The performance of the impedance controller for obstacle avoidance is also discussed. The major advantage of the proposed impedance control for the motion of a mobile vehicle is that the trajectory is generated rather than preplanned and is corrected to avoid obstacles in real time. A MULTIPLEXED TWO-WAY SOLID COMMUNICATIONS LINK FOR TELEOPERATED ROBOTS **c63**
J. J. Grodski and D. Stampe *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 266-271 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Remote mobile investigator robots used by the Canadian Forces in explosive ordnance disposal tasks comprise a remote unit and a control station. In the system's original version, the control station and the remote unit were linked by an 80-m heavy electrical cable spooled at the control station. This cable provides the control, video, and audio communications link between the two units. A new multiplexer and demultiplexer system was developed to reduce the size of the cable, extend the range of the communication link, and minimize the cost of the link. The link uses a single 75-ohm coaxial cable to carry multiplexed audio and control signals to the remote unit and video and audio back to the control station. Critical design features and characteristics of the system are described. Preliminary tests of the system indicate that performance is very good. The link will be proposed for implementation in the remote mobile investigator or other explosive ordnance disposal systems requiring a solid communications link. The link can also be readily adapted to other teleoperated systems with similar communications requirements. Author (CISTI)

UNMANNED VEHICLE MOBILITY: LIMITS OF AUTONOMOUS NAVIGATION
A. W. McCormac, D. M. Hanna, and J. McFee *In its* Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 301-310 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

Considerable research is being conducted on the development of unmanned vehicles for military and civilian applications, particularly for hostile environments. It is desirable to produce a vehicle which can select its own route, not requiring remote navigation, but then it would be required to sense its surroundings. Although imaging systems and modern computers make this possible, the extreme data processing demands usually make it impractical. It is suggested that an inverse relationship exists between vehicle mobility and the complexity of the autonomous navigation system required for an unmanned vehicle. An overview of vehicle navigation is presented which shows the degree to which navigation is affected by increasing inherent mobility. If the inherent mobility of a vehicle is greatly enhanced, the scene image processing requirements and navigational

computations are greatly simplified. This means the vehicle path selection and speed and steering adjustments may be made more quickly, resulting in higher vehicle speeds whenever possible. Combined with reduced deviation from the intended path, this would greatly increase the speed of the vehicle from one given point to another, suggesting that high speed autonomous navigation may be feasible. ELECTROCHEMICAL POWER SOURCE (EPS) SELECTION FOR ENERGETICALLY INDEPENDENT ROBOTS (EIR): A SYSTEMATIC APPROACH c33
P. R. Roberge and K. A. Sosin *In* Defence Research Establishment Suffield, Proceedings of the 3rd Conference on Military Robotic Applications 1991 p 318-326 (For primary document see N94-30275 08-37)
Avail: Issuing Activity (Defence Research Establishment Suffield, P.O. Box 4000, Medicine Hat, AB T1A 8K6 Canada)

The term energetically independent robots (EIR) is used for robots that can perform a mission while depending only on energy stored and carried by themselves. In the case of long missions, periodical refuelling or recharging is admissible. The selection of electrochemical power sources for EIRs constitutes a serious engineering challenge. The selection process is a compromise between various and contradictory requirements. A structured approach to the selection process is introduced. The key selection factors considered in this approach are mission duration and environment, total energy demand, power profile, acceptable weight and size, and reliability. A critical analysis of existing electrochemical power sources with respect to these considerations is presented, revealing the applicability of fuel cells for a wide range of EIR's. Contemporary fuel cell technology offers lightweight electrochemical power sources capable of delivering large amounts of energy at relatively high power rates. Those sources can be combined with others, demonstrating high resistance to overloading, thus creating hybrid power supplies potentially better than classic internal combustion engines. Advantages of those sources are quietness and low heat emission. Author (CISTI)

The development and validation of an advanced algorithm for the simulation of the dynamics of flexible spacecraft/space manipulator systems are outlined. The requirements imposed during the development of the present prototype dynamics simulator led to the modification and implementation of an existing linear recursive algorithm ('order-N' algorithm), which requires a computational effort proportional to the number of component bodies in the system. Starting with the Lagrange form of the d'Alembert principle, a parametric form which is found to yield, among others, the basic forms of the Newton-Euler, the d'Alembert, and the Gauss dynamics principles was deduced. It is shown how the application of each of the latter three principles can be made to lead graciously to be desired order-N agorithm for the flexible multibody system. ESA

IN-CYLINDER GAS VELOCITY MEASUREMENTS COMPARING CRANKCASE AND BLOWER SCAVENGING IN A FIRED TWO-STROKE CYCLE ENGINE
P. C. Miles, R. M. Green, and P. O. Witze 1994 20 p Presented at the Society of Automotive Engineers (SAE) Congress and Exposition, Detroit, MI, 28 Feb. - 3 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-76DP-00789)
(DE94-005752; SAND-94-8521C; CONF-940242-2) Avail: CASI HC A03

The in-cylinder flow field of a Schnuerle (loop) scavenged two-stroke engine has been examined under conditions simulating both blower and crankcase driven scavenging. Measurements of the radial component of velocity were obtained along the cylinder centerline during fired operation at delivery ratios of 0.4, 0.6, and 0.8. Both mean velocity profiles and root mean square velocity fluctuations near top center show a strong dependence on the scavenging method. Complementary in-cylinder pressure measurements indicate that combustion performance is better under blower driven scavenging for the engine geometry studied. DOE

Viewgraphs from a presentation on transportation control measures (TCM) to facilitate the use of alternative-fuel vehicles (AFV) are given. Types of TCM's that pertain to AFV exemptions are: parking fees and restrictions, high occupancy vehicle lanes, fuel taxes, and possibly congestion pricing and time of day and day of week restrictions. The degree to which these measures will impact AFV production by the year 2010 is predicted. DOE

PARAMETER IDENTIFICATION OF THE ROTORDYNAMIC COEFFICIENTS OF HIGH-REYNOLDS-NUMBER HYDROSTATIC BEARINGS Ph.D. Thesis
Constantinos Rouvas 1993 87 p
Avail: Univ. Microfilms Order No. DA9328796

The research presented here concentrates on experimental and analytical methods to identify the twelve rotordynamic coefficients of high-Reynolds-number hydrostatic bearings. Fluid-flow-induced noise (turbulence, cavitation) presents a significant problem in testing these bearings, since this noise exists in the same frequency range as the test signals. This common frequency range eliminates the possibility of rejecting the noise through filtering. A frequency-domain analysis method has been developed to extract the rotordynamic coefficients from data obtained by multi-frequency sequential excitation testing. Power-spectral-density estimates are used to reject noise that is independent of the applied excitation. The method is verified experimentally by single-frequency excitation, and repeatability tests. A second power-spectral-density based identification method has been developed and applied to simultaneous excitation test data. Here, two independent random excitations are applied simultaneously to the bearing, and their effects are separated by computing appropriate power-spectral-density estimates, while, at the same time, maintaining excellent noise rejection properties. This method yields results identical to the sequential excitation procedure, and reduces the actual test and analysis times by one half. Last, an analysis method in the time domain has been developed and implemented. In essence it is a direct application of least squares to the bearing housing equations of motion. For this method, it is shown that for the low-frequency noise present in the measurements, differentiation of the signals is acceptable, and preferable over integration. The twelve rotordynamic coefficients are obtained from a recursive formulation of least squares, and the results are shown to have acceptable convergence. Also, the coefficients extracted from this method are found to reconstruct the bearing response more accurately than the coefficients extracted from the power-spectral-density methods.

KINEMATIC ANALYSIS OF PLATFORM-TYPE ROBOTIC MANIPULATORS Ph.D. Thesis
Xiaolun Shi 1993 302 p
(ISBN-0-315-78703-1) Avail: Univ. Microfilms Order No. DANN78703

New methods are developed for the kinematic analysis of serial and platform-type parallel robotic manipulators, including forward and inverse kinematic solutions, singularity identifications and workspace evaluation. Differences between serial and platform-type parallel manipulators, which can provide substantially improved end-point rigidity compared with the

conventional serial robotic arms, are addressed. The problem of determining the screw parameters of rigid body motion from initial and final position data is discussed, as a basis to search for a general and efficient procedure to solve the complex forward kinematics problem of platform-type manipulators. Several Screw-Theory based approaches for solving the inverse instantaneous problem of 6 DOF serial manipulators are studied and compared in terms of their computational efficiency, accuracy, sensitivity to data error and capability of dealing with singularities. A modified Vector Decomposition method is then proposed for solving the IIK problem and for singularity analysis of serial kinematic chains, the method is especially effective when applied to the wrist partitioned serial manipulators, which are essential components to any platform-type parallel manipulators. By using the data of three point positions, velocities, and accelerations of the end effector a general method is developed for solving the forward kinematics problem, including position, velocity and acceleration kinematics, of platform-type manipulators. The solution procedure can be applied to a wide variety of platform-type manipulators such as the 6 DOF Steward Platform manipulator and other models. It is found that while the solution for the forward position kinematics of a platform-type manipulator can be obtained by solving a non-linear system of equations, the closed-form solutions for forward rate and acceleration kinematics can be found by solving a system of linear equations. Based on the proposed kinematic formulations, an algorithm for detecting the boundaries of reachable workspace of platform-type manipulators is introduced, using a new concept of the Geometric Envelope. As the algorithm is based on the relatively simple inverse kinematic solution of platform-type manipulators, it is, in general, more efficient and easier to implement than any other existing methods for this purpose. Singular configurations of platform-type manipulators are discussed and a general analytical condition for configuration singularity is derived, based on the forward rate kinematics of platform-type manipulators. It is believed that this is one of the most general analytical expressions so far for singular configurations of a platform-type parallel manipulator. Dissert. Abstr.

ROTOR INSTABILITY INDUCED BY DEAD BAND CLEARANCE IN BEARING SUPPORTS Ph.D. Thesis
Yao-Qun Lin 1993 203 p
Avail: Univ. Microfilms Order No. DA9328763

Rotor instability, or rotor nonsynchronous natural frequency vibration, is of major concern in the rotor dynamics field. Efforts have been made continuously to explain this phenomenon since it was identified more than seventy years ago. To date, rotor instability vibration has been almost ascribed to two mechanisms, i.e., internal friction effects and fluid actions. It has been predicted by some investigations that dead band clearance in bearing supports can induce only sub and/or super harmonics tracking the synchronous speed and does not cause the nonsynchronous (non-harmonic) natural frequency vibration. It is shown, however, in this dissertation that dead band clearance in ball bearing supports can induce rotor nonsynchronous natural frequency vibration. The computer simulations show that in a limited speed range, the ball-bearing outer race of an unbalanced rotor may leave (tight-loose) then touch (loose-tight) the housing surface and induce an internal impact. Internal impacts will excite the natural frequency vibration of the rotor, which is independent of the rotor synchronous vibration and will reach a limit cycle due to system's damping. Beyond the speed range, the nonsynchronous natural frequency disappears. Half-frequency vibration is also predicted by the computer simulations. It is shown that the half-frequency vibration is induced by the nonlinear coupling between the equations of motion due to dead band clearance. Experiments with a rotor supported on ball bearings with dead band clearance are conducted. The experimental results agree well with the theoretical predictions. The nonsynchronous natural frequency vibration of ball-bearing supported rotors (without seals) has been traditionally explained as internal friction induced rotor instability. The classical internal friction theory is discussed in this dissertation. It is claimed here that what is predicted by the classical linear theory on internal friction is a divergent (Liapunov unstable) response and hence is unmeasurable. But rotor instability vibration, which has two significant components at the synchronous and the natural frequencies, is measurable and hence is Liapunov stable. Dissert. Abstr.

INVESTIGATION OF THE TECHNOLOGY DEVELOPMENT STATUS OF ALTERNATE FUEL VEHICLES
Mar. 1993 73 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-744237; ETDE/JP-MF-94744237) Avail: CASI HC A04

The main purpose of the introduction of alternate fuel vehicles is to contribute to the reduction of pollution, the alternate energy for petroleum, and the energy savings. This report describes the development status of methanol, natural gas, and electric vehicles, which have high potential as alternate fuel vehicles. Characteristics of alternate fuel vehicles are compared by using the same factors on the basis of technological data. Outlines of individual alternate fuel vehicles are illustrated. Then, practicabilities of the alternate fuel vehicles are compared with each other, as for the output and energy densities, maximum output and torque of motors, power performance, specific consumption of energy, driving distance, initial cost, running cost and life cycle cost, convenience of fuel and energy supply, low pollution, and health effects. INTEGRATED STRUCTURE/CONTROL DESIGN OF NONRIGID ROBOT ARMS FOR HIGH-SPEED MANIPULATION Ph.D. Thesis
Jahng-Hyon Park 1992
Avail: Issuing Activity (MIT Libraries, Rm. 14-0551, Cambridge, MA 02139-4307)

In assembly of PC boards and VLSI's, there is a great need for ultrahigh speed robots that can significantly reduce the cycle time and thereby increase productivity. To meet this demand, a technical breakthrough is necessary for arm design, which substantially departs from the traditional design paradigm. Traditionally, arm linkage and drive mechanisms are designed first followed by control design. Structure design, while it is optimal with respect to kinematics and statics, is not always optimal from the control standpoint. There exists intricate interactions between mechanisms and controls, which must be taken into account in designing the system. To achieve high performance, a cohesive and comprehensive design method that integrates both structure and control design is necessary. First, flexibility of arm links is included in the model to consider the dynamic deflections in high speed manipulation. An actuator relocation method for improving flexible arm dynamics is presented. The endpoint control of a flexible arm has been known as a nonminimum phase system due to the noncollocated sensor and actuator. By relocating the actuator near the endpoint, the system can be changed to a minimum phase system. Pole-zero locations of a single-link flexible arm are obtained for the actuator types (force and torque) and the actuator locations. Pole-zero configurations and their effect on control are analyzed with regard to the location of the actuation point. The guidelines for the actuator locations are developed with respect to the operation bandwidth, stability, and controllability. An integrated approach to the concurrent design of arm structure and control is presented. To achieve high speed positioning, a technique is developed in which comprehensive design parameters describing arm link geometry, actuator locations, and feedback gains are optimized with respect to the settling time of the system. A two-link, nonrigid arm is analyzed and a simple dynamic model representing rapid positioning processes is obtained. Optimal feedback gains minimizing the settling times are obtained as functions of structural parameters involved in the dynamic model. The structural parameters are then optimized using a nonlinear programming technique in order to obtain an overall optimal performance. The resultant arm design shows an outstanding performance, which is otherwise unattainable if one designs the structure and control separately. Dissert. Abstr.

COMPRESSED NATURAL GAS FUELED VEHICLES: THE HOUSTON EXPERIENCE
1993 141 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG02-90CE-27504)
(DE94-005804; DOE/CE-27504/T11) Avail: CASI HC A07

Houston's experience in defining the compressed natural gas fueled vehicle research scope and issues is described. It details the ways in which the project met initial expectations and how the project scope,

focus, and duration were adjusted in response to unanticipated results. It provides examples of real world successes and failures in efforts to commercialize basic research in adapting a proven technology (natural gas) to a noncommercially proven application (vehicles). Phase one of the demonstration study investigates, develops, documents, and disseminates information regarding the economic, operational, and environmental implications of utilizing compressed natural gas (CNG) in various truck fueling applications. The four truck classes investigated are light duty gasoline trucks, medium duty gasoline trucks, medium duty diesel trucks, and heavy duty diesel trucks. The project researches aftermarket CNG conversions for the first three vehicle classes and original equipment manufactured (OEM) CNG vehicles for light duty gasoline and heavy duty diesel classes. In phase two of the demonstration project, critical issues are identified and assessed with respect to implementing use of CNG fueled vehicles in a large vehicle fleet. These issues include defining changes in local, state, and industry CNG fueled vehicle related codes and standards; addressing vehicle fuel storage limitations; using standardized vehicle emission testing procedures and results; and resolving CNG refueling infrastructure implementation issues and related cost factors. The report identifies which CNG vehicle fueling options were tried and failed and which were tried and succeeded, with and without modifications. The conclusions include a caution regarding overly optimistic assessments of CNG vehicle technology at the initiation of the project. DOE

The damping ratio of automobile shock absorbers is studied. The inadequacy of a first order model for an automobile shock absorption system is demonstrated and a wheel shock absorption model is considered. From analysis of the frequency response, and from the phase diagram in particular, the relation sought between damping ratio and critical car parameters is obtained. ESA

A CONTROL METHOD FOR BILATERAL TELEOPERATING SYSTEMS Ph.D. Thesis
Yesayahu Strassberg 1992 263 p
(ISBN-0-315-78705-8) Avail: Univ. Microfilms Order No. DANN78705

The thesis focuses on control of bilateral master-slave teleoperators. The bilateral control issue of teleoperators is studied and a new scheme that overcomes basic unsolved problems is proposed. A performance measure, based on the multiport modeling method, is introduced in order to evaluate and understand the limitations of earlier published bilateral control laws. Based on the study evaluating the different methods, the objective of the thesis is stated. The proposed control law is then introduced, its ideal performance is demonstrated, and conditions for stability and robustness are derived. It is shown that stability, desired performance, and robustness can be obtained under the assumption that the deviation of the model from the actual system satisfies certain norm inequalities and the measurement uncertainties are bounded. The proposed scheme is validated by numerical simulation. The simulated system is based on the configuration of the RAL (Robotics and Automation Laboratory) telerobot. From the simulation results it is shown that good tracking performance can be obtained. In order to verify the performance of the proposed scheme when applied to a real hardware system, an experimental setup of a three degree of freedom master-slave teleoperator (i.e. three degree of freedom master and three degree of freedom slave robot) was built. Three basic experiments were conducted to verify the performance of the proposed control scheme. The first experiment verified the master control law and its contribution to the robustness and performance of the entire system. The second experiment demonstrated the actual performance of the system while performing a free motion teleoperating task. From the experimental results, it is shown that the control law has good performance and is robust to uncertainties in the models of the master and slave.

KINEMATICS AND FORCE ANALYSIS OF A ROBOT HAND BASED ON AN ARTIFICIAL BIOLOGICAL CONTROL SCHEME Ph.D. Thesis
Man Guen Kim 1993 263 p
Avail: Univ. Microfilms Order No. DA9320188

An artificial biological control scheme (ABCS) is used to study the kinematics and statics of a multifingered hand with a view to developing an efficient control scheme for grasping. The ABCS is based on observation of human grasping, intuitively taking it as the optimum model for robotic grasping. A final chapter proposes several grasping measures to be applied to the design and control of a robot hand. The ABCS leads to the definition of two modes of the grasping action: natural grasping (NG), which is the human motion to grasp the object without any special task command, and forced grasping (FG), which is the motion with a specific task. The grasping direction line (GDL) is defined to determine the position and orientation of the object in the hand. The kinematic model of a redundant robot arm and hand is developed by reconstructing the human upper extremity and using anthropometric measurement data. The inverse kinematic analyses of various types of precision and power grasping are studied by replacing the three-link with one virtual link and using the GDL. The static force analysis for grasping with fingertips is studied by applying the ABCS. A measure of grasping stability, that maintains the positions of contacts as well as the configurations of the redundant fingers, is derived. The grasping stability measure (GSM), a measure of how well the hand maintains grasping under the existence of external disturbance, is derived by the torque vector of the hand calculated from the external force applied to the object. The grasping manipulability measure (GMM), a measure of how well the hand manipulates the object for the task, is derived by the joint velocity vector of the hand calculated from the object velocity. The grasping performance measure (GPM) is defined by the sum of the directional components of the GSM and the GMM. Finally, a planar redundant hand with two fingers is examined in order to study the various postures of the hand performing pinch grasping by applying the GSM and the GMM. Dissert. Abstr.

The fields of reliability analysis and risk assessment have grown dramatically since the 1970's. There are now bodies of literature and standard practices which cover quantitative aspects of system analysis such as failure rate and repair models, fault and event tree generation, minimal cut sets, classical and Bayesian analysis of reliability, component and system testing techniques, and decomposition methods. In spite of the growth in the sophistication of reliability models, however, little has been done to integrate optimization models within a reliability analysis framework. That is, often reliability models focus on characterization of system structure in terms of topology and failure/availability characteristics of components. A number of approaches have been proposed to help identify the components of a system that have the largest influence on overall system reliability. While this may help rank order the components, it does not necessarily help a system design team identify which components they should improve to optimize overall reliability (it may be cheaper and more effective to focus on improving two or three components of smaller importance than one component of larger importance). In this paper, we present an optimization model that identifies the components to be improved to maximize the increase in system MTBF, subject to a fixed budget constraint. A dual formulation of the model is to minimize cost, subject to achieving a certain level of system reliability. DOE

DEVELOPMENT OF ALTERNATING CURRENT POTENTIAL DROP (ACPD) PROCEDURES FOR CRACK DETECTION IN ALUMINUM AIRCRAFT PANELS Final Report, May - Dec. 1990
D. A. Jablonski Dec. 1993 108 p
(Contract DTRS57-89-D-00007)
(AD-A275755; DOT-VNTSC-FAA-93-9; DOT/FAA/CT-93/76) Avail: CASI HC A06/MF A02

The Alternating Current Potential Drop (ACPD) method is investigated as a means of making measurements in laboratory experiments on the initiation and growth of multiple site damage (MSD) cracks in a common aluminum alloy used for aircraft construction. Procedures for instrumenting MSD test specimens are recommended. The ACPD method is found to be capable of the following: (1) detecting crack initiation at a crack length of the order of 1 mm; (2) monitoring crack propagation at a resolution of the order of 5 micrometers; and (3) providing an indirect measurement of crack extension in R-curve type tests of fastener hole details. ALGORITHMS FOR TREATING REDUNDANCY IN REPAIRABLE AND NON-REPAIRABLE SYSTEMS
James E. Campbell, Dennis E. Longsine, and Joel Atkins Oct. 1993 75 p
(Contract DE-AC04-94AL-85000)
(DE94-005289; SAND-93-1822) Avail: CASI HC A04/MF A01

This report presents equations and computational algorithms for analyzing the reliability of several forms of redundancy in repairable and non-repairable systems. For repairable systems, active, standby, and R of N redundancy with and without repair are treated. For non-repairable systems, active, standby, and R of N redundancy are addressed. These equations can be used to calculate mean time between failures, mean time to repair, and reliability for complex systems involving redundancy. DOE

US-Patent-Appl-SN-134444) Avail: CASI HC A03/MF A01

A flux-focusing electromagnetic sensor which uses a ferromagnetic flux-focusing lens simplifies inspections and increases detectability of fatigue cracks and material loss in high conductivity material is presented. The unique feature of the device is the ferrous shield isolating a high-turn pick-up coil from an excitation coil. The use of the magnetic shield is shown to produce a null voltage output across the receiving coil in the presence of an unflawed sample. A redistribution of the current flow in the sample caused by the presence of flaws, however, eliminates the shielding condition and a large output voltage is produced, yielding a clear unambiguous flaw signal. The maximum sensor output is obtained when positioned symmetrically above the crack. Hence, by obtaining the position of the maximum sensor output, it is possible to track the fault and locate the area surrounding its tip. The accuracy of tip location is enhanced by two unique features of the sensor; a very high signal-to-noise ratio of the probe's output which results in an extremely smooth signal peak across the fault, and a rapidly decaying sensor output outside a small area surrounding the crack tip which enables the region for searching to be clearly defined. Under low frequency operation, material thinning due to corrosion damage causes an incomplete shielding of the pick-up coil. The low frequency output voltage of the probe is therefore a direct indicator of the thickness of the test sample. NASA

A neural network tool was developed to automate the Non Destructive Testing (NDT) of aeronautical structures carried out with the SIAM system. The SIAM system is used to reveal splits in longitudinal metal joints on the Airbus fuselage. The integration of the neural net tool within the SIAM control system is considered possible. The automatic diagnostic should provide the operator with an aid which will permit a greater reliability of maintenance control. The diagnostic performed with this tool would be rapid;: the control of 30,000 rivets on the Airbus fuselage would take approximately 45 minutes. ESA

Int-Patent-Class-G01N-29/28) Avail: US Patent and Trademark Office

A method for indicating disbonds in joint regions is discussed. A critical bondline region is located between a first material and a second material having a higher acoustic impedance than the first material. A form member having an acoustic impedance which is substantially similar to the first material has a first face which is form fitted to a surface of the first material opposite to and non-parallel with the critical bondline region. The form member has an opposite second face which is shaped to be parallel to the critical bondline region. Transducers are acoustically coupled to the second face of the form member to generate an ultrasonic tone burst through the acoustically similar form member and first material which is reflected by the critical bondline region. This reflected tone burst is received

and a resulting signal is compared with a normal signal for no disbond to determine the presence of an unacceptable disbond.

Infrared thermography is a relatively new technique for nondestructive inspection of parts and components. It allows detection of the presence of subsurface defects such as debonding, delaminations, and inclusions. Nevertheless, certain problems must be resolved before this material inspection technique can be made universal. One of these problems concerns the deposition of energy on the surface of the samples being analyzed. In effect, it is not easy to find an inexpensive and powerful source which also achieves a uniform deposition of energy. Laser sweeping might be possible, but at a prohibitive cost. Special 1000-W bulbs can be used if a calibration of the spatial distribution of energy in the measurement zone is carried out. This latter approach has been followed in a study of spatial calibration of the deposition of thermal energy (read by the infrared camera) and modelling of internal heat transfer, so that the response of the analyzed parts could be characterized a-priori. A simple finite difference model was used in the theoretical part of the study. The experimental and theoretical results obtained are promising and open up other interesting applications for thermography. CISTI

The focus of the work is aimed at two scientific issues. The primary emphasis is directed to development of a method which enables the detection of ductile crack initiation, and hence, the energy-based fracture toughness, by applying an optical crack opening displacement (COD) measuring device. It is claimed that the Double Displacement Ratio (DDR), i.e., the ratio of crack opening displacement vs. specimen displacement, indicates the onset of ductile crack growth initiation in a way which is easy and reliable enough to apply in transition and upper shelf regions of a fracture toughness transition temperature curve. The method is extensively verified by experimental and analytical investigations, and compared with other single specimen methods used for dynamic fracture toughness determination. NTIS

Measurement of energy flow in acoustical and vibrational fields is usually based on the detection of one linear field quantity (e.g. sound pressure) and its spatial gradient, two transducers being used for the measurement. This report first reviews the quantities which can be obtained from the measurement of acoustical intensity with a two-microphone probe: intensity and the energy densities. A set of 'field descriptors', relative quantities giving a measure of propagating (active) character of the waves in the sound field, is proposed. These energetic quantities are based entirely on the transversal velocity measured and the gradient of that velocity, and are available when the two-transducer method of bending wave intensity is used. Examples of the energy densities and field descriptors measured in an aluminum plate are presented, and proposals for further work are given. NTIS

VISCOUS AND ELASTIC-PLASTIC MATERIAL MODEL IN THE ABAQUS
Kari Santaoja 1993 54 p
(PB94-132347; VTT/PUB-144; ISBN-951-38-4382-3) Copyright Avail: CASI HC A04/MF A01

The implementation of constitutive equations into a structural analysis computer program is investigated. The material model under consideration describes pure linear elastic, elastic-plastic, and viscous deformation mechanisms. The elastic-plastic material model assumes isotropic hardening and the uniaxial stress-strain curve is bilinear. The von Mises yield condition is applied. Viscous deformation is described by the equation proposed by Le Gac and Duval. This model is coded into the ABAQUS finite element method program. The time integration is carried out by the Euler forward method. The computed examples show that the implementation is carried out successfully. NTIS

COMPOSITE LOAD SPECTRA FOR SELECT SPACE PROPULSION STRUCTURAL COMPONENTS Final Report
Hing W. Ho and James F. Newell Mar. 1994 269 p
(Contract NAS3-26371; RTOP 584-03-11)
(NASA-CR-194476; E-8621; NAS 1.26:194476) Avail: CASI HC A12/MF A03

Generic load models are described with multiple levels of progressive sophistication to simulate the composite (combined) load spectra (CLS) that are induced in space propulsion system components, representative of Space Shuttle Main Engines (SSME), such as transfer ducts, turbine blades and liquid oxygen (LOX) posts. These generic (coupled) models combine the deterministic models for composite load dynamic, acoustic, high-pressure and high rotational speed, etc., load simulation using statistically varying coefficients. These coefficients are then determined using advanced probabilistic simulation methods with and without strategically selected experimental data. The entire simulation process is included in a CLS computer code. Applications of the computer code to various components in conjunction with the PSAM (Probabilistic Structural Analysis Method) to perform probabilistic load evaluation and life prediction evaluations are also described to illustrate the effectiveness of the coupled model approach. PLANE STRESS STABLE CRACK GROWTH AND J-INTEGRAL/HRR FIELD
G. B. May and A. S. Kobayashi Dec. 1993 40 p
(Contract N00014-89-J-1276)
(AD-A275761; UWA/DME/TR-93-74) Avail: CASI HC A03/MF A01

Moire interferometry with line densities of 1200 and 40 lines per mm was used to determine the two orthogonal displacements surrounding a stably extending crack in a 2024-T3 aluminum alloy, single edge-cracked specimen. The test protocol consisted of using the fine moire grating prior to and up to the onset of crack extension and the coarse moire grating for the ensuing crack extension up to delta(a) = 6 mm. The displacement fields were used to compute the J-integrals for various contours during crack tip blunting and crack extension. As expected, the far-field J-integral value prior to stable crack growth coincided with the LEFM strain energy release rate, G, and validated the experimental procedure. However, the J values obtained from the near tip contour increased slowly while the far field J values increased rapidly with increasing stable crack growth. The HRR displacement field was computed from the experimentally determined far field J. The HRR displacement field agreed with the measured displacement field prior to stable crack growth since J = G. However, the HRR horizontal displacement field progressively deviated from the measured values with crack extension. DTIC

NUMERICAL AND EXPERIMENTAL INVESTIGATION OF THE BENDING RESPONSE OF THIN-WALLED COMPOSITE CYLINDERS Interim Report No. 95, Aug. 1988 - Sep. 1993
J. P. Fuchs, M. W. Hyer, and J. H. Starnes, Jr. Sep. 1993 193 p
(Grant NAG1-343)
(NASA-CR-195730; NAS 1.26:195730; CCMS-93-19; VPI-E-93-11) Avail: CASI HC A09/MF A03

A numerical and experimental investigation of the bending behavior of six eight-ply graphite-epoxy circular cylinders is presented. Bending is induced by applying a known end-rotation to each end of the cylinders, analogous to a beam in bending. The cylinders have a nominal radius of 6 inches, a length-to-radius ratio of 2 and 5, and a radius-to-thickness ratio of approximately 160. A (+/- 45/0/90)S quasi-isotropic layup and two orthotropic layups, (+/- 45/0 sub 2)S and (+/- 45/90 sub 2)S, are studied. A geometrically nonlinear special-purpose analysis, based on Donnell's nonlinear shell equations, is developed to study the prebuckling responses and gain insight into the effects of non-ideal boundary conditions and initial geometric imperfections. A geometrically nonlinear finite element analysis is utilized to compare with the prebuckling solutions of the special-purpose analysis and to study the buckling and post buckling responses of both geometrically perfect and imperfect cylinders. The imperfect cylinder geometries are represented by an analytical approximation of the measured shape imperfections. Extensive experimental data are obtained from quasi-static tests of the cylinders using a test fixture specifically designed for the present investigation. A description of the test fixture is included. The experimental data are compared to predictions for both perfect and imperfect cylinder geometries. Prebuckling results are presented in the form of displacement and strain profiles. Buckling end-rotations, moments, and strains are reported, and predicted mode shapes are presented. Observed and predicted moment vs. end-rotation relations, deflection patterns, and strain profiles are illustrated for the post buckling responses. It is found that a geometrically nonlinear boundary layer behavior characterizes the prebuckling responses. The boundary layer behavior is sensitive to laminate orthotropy, cylinder geometry, initial geometric imperfections, applied end-rotation, and non-ideal boundary conditions. Buckling end-rotations, strains, and moments are influenced by laminate orthotropy and initial geometric imperfections. Measured buckling results correlate well with predictions for the geometrically imperfect specimens. The postbuckling analyses predict equilibrium paths with a number of scallop-shaped branches that correspond to unique deflection patterns. The observed postbuckling deflection patterns and measured strain profiles show striking similarities to the predictions in some cases. Ultimate failure of the cylinders is attributed to an interlaminar shear failure mode along the nodal lines of the postbuckling deflection patterns. Author

A MODELING STUDY OF THE EFFECT OF STRESS STATE ON VOID LINKING DURING DUCTILE FRACTURE
A. B. Geltmacher, D. A. Koss, P. Matic, and M. G. Stout 28 Jan. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1414)
(AD-A275505; TR-8) Avail: CASI HC A03

Specimens containing arrays of through-thickness holes are used to model aspects of void linking during ductile, microvoid fracture. Specifically, the contrasting deformation and fracture behavior of sheet specimens containing either pairs or pseudo-random arrays of equi-sized holes is examined in both uniaxial and equal-biaxial tension utilizing experiment as well as computer simulation. Our results show for this plane-stress situation that hole linking is always caused by flow localization within the ligaments between neighboring holes. The imposed strains to initiate flow localization and subsequent ligament failure are sensitive to stress state (uniaxial versus biaxial), strain hardening, and the location of the neighboring hole(s). A significant observation is the influence of stress state on the multidirectionality of hole linking paths. As a result, increasing the biaxial component of the stress-state increases the number of holes that can participate in a hole linking process increases. A related and subtle implication to microvoid fracture is that the strain range over which void linking occurs decreases with increasing triaxiality of the stress state; in effect, after the initiation of void linking, its propagation is accelerated under biaxial or triaxial tension. AN ANALYSIS OF ISOTHERMAL, BITHERMAL, AND THERMOMECHANICAL FATIGUE DATA OF HAYNES 188 AND B1900+Hf BY ENERGY CONSIDERATIONS
V. M. Radhakrishnan (Indian Inst. of Tech., Madras.), Sreeramesh Kalluri (Sverdrup Technology, Inc., Brook Park, OH.), and Gary R. Halford Sep. 1993 25 p
(Contract NAS3-25266; RTOP 505-63-5B)
(NASA-TM-106359; E-8153; NAS 1.15:106359) Avail: CASI HC A03/MF A01

The low-cycle fatigue behavior of Haynes 188 and B1900+Hf under isothermal, bithermal, and thermomechanical loading conditions has been analyzed on the basis of the total hysteresis energy expended per cycle. It has been observed that in the case of isothermal fatigue the total hysteresis energy correlates well with the fatigue life. In the case of bithermal

'high rate' fatigue, for a given total hysteresis energy per cycle, the fatigue life is equal to or greater than the isothermal fatigue life at the maximum bithermal temperature. This observation could be used to establish a lower bound on life for design purposes. In one case of bithermal creep-fatigue and in thermomechanical fatigue, the life is shorter than that corresponding to the isothermal life at the maximum temperature. The energy supplied, per se, may not always give a systematic correlation with the fatigue life in the cases where time-dependent creep and environmental effects are encountered. Thus, in bithermal creep-fatigue and thermomechanical fatigue, the role of creep and environment and their dependence on the energy supplied have to be properly accounted for before the energy term can be used for life prediction. AN ANISOTROPIC EXTENSION OF BODNER'S MODEL OF VISCOPLASTICITY: MODEL DEVELOPMENT Final Report
David N. Robinson Mar. 1994 17 p
(Grant NAG3-379; RTOP 505-63-12)
(NASA-CR-195289; E-8649; NAS 1.26:195289) Avail: CASI HC A03/MF A01

An anisotropic viscoplasticity model is developed as an extension of the well known Bodner model. The extension is made by replacing the effective stress of the isotropic Bodner model by one involving invariants for transverse isotropy. The resulting model retains the simplicity of Bodner's in the ease with which the material constants are determined experimentally. It allows a representation of strong initial anisotropy yet is based on the scalar state variable under the assertion that induced anisotropy is negligible relative to the strong initial anisotropy. Temperature dependence is taken as in the original Bodner theory. Account is made of fiber volume fraction through nonlinear rules of mixture applied to the stress history and anisotropy parameters. Focus is on the theoretical development of the model, however, application to a W/Cu composite is in progress and will be reported as a sequel to this report. Author

PROBABILISTIC MATERIAL STRENGTH DEGRADATION MODEL FOR INCONEL 718 COMPONENTS SUBJECTED TO HIGH TEMPERATURE, MECHANICAL FATIGUE, CREEP AND THERMAL FATIGUE EFFECTS Final Report
Callie Corinne Schei Bast Mar. 1994 75 p
(Grant NAG3-867; RTOP 584-03-11)
(NASA-CR-195284; E-8629; NAS 1.26:195284) Avail: CASI HC A04/MF A01

This thesis presents the on-going development of methodology for a probabilistic material strength degradation model. The probabilistic model, in the form of a postulated randomized multifactor equation, provides for quantification of uncertainty in the lifetime material strength of aerospace propulsion system components subjected to a number of diverse random effects. This model is embodied in the computer program entitled PROMISS, which can include up to eighteen different effects. Presently, the model includes four effects that typically reduce lifetime strength: high temperature, mechanical fatigue, creep, and thermal fatigue. Statistical analysis was conducted on experimental Inconel 718 data obtained from the open literature. This analysis provided regression parameters for use as the model's empirical material constants, thus calibrating the model specifically for Inconel 718. Model calibration was carried out for four variables, namely, high temperature, mechanical fatigue, creep, and thermal fatigue. Methodology to estimate standard deviations of these material constants for input into the probabilistic material strength model was developed. Using the current version of PROMISS, entitled PROMISS93, a sensitivity study for the combined effects of mechanical fatigue, creep, and thermal fatigue was performed. Results, in the form of cumulative distribution functions, illustrated the sensitivity of lifetime strength to any current value of an effect. In addition, verification studies comparing a combination of mechanical fatigue and high temperature effects by model to the combination by experiment were conducted. Thus, for Inconel 718, the basic model assumption of independence between effects was evaluated. Results from this limited verification study strongly supported this assumption. Author (revised)

MEASUREMENT AND MODELLING OF BOLTED JOINT STRESS RELAXATION IN PLASTICS
A. Cook, D. Dawson, and B. C. Duncan Jul. 1993 49 p
(PB94-124849; DMM(A)-109) Avail: Issuing Activity (National Technical Information Service (NTIS))

The loss of joint integrity caused by viscoelastic stress relaxation limits the service life of plastic components bolted to dissimilar materials. A technique, which incorporates an integral load cell, to measure the stress relaxation properties of bolted polymer components over extended time periods at temperatures of up to 150 C was developed. Models were developed to extrapolate the measured stress relaxation, thus providing an estimate of the service life. At elevated temperatures, isothermal shrinkage of the polymer can have a significant impact on the load, contrary to what was believed previously. Phenolic thermostat housings undergoing the standard post-cure (seven hours at 170 C) should have service lives of 3 years at operating temperatures of up to 100 C. NTIS

PORTABLE ELECTRONICALLY BASED METHOD FOR THE NONDESTRUCTIVE REMOTE SENSING OF CREVICE CORROSION Final Report, 27 Apr. - 31 Oct. 1993
D. Hodko, M. Novak, C. C. Andrews, O. J. Murphy, and G. D. Hitchens 31 Oct. 1993 30 p
(Contract N00014-93-C-0067)
(AD-A275403) Avail: CASI HC A03/MF A01

Corrosion in the crevices of gasketed joints in the presence of sea-water has been particularly troublesome for the Navy in pipelines. Some of the existing non-destructive techniques can be used without entering the pipeline system but most of them suffer from low signal-to-noise ratios due to spurious signals caused by scattering on rough-pitted surfaces. The main advantages of four-point probe pulsed current resistance measurements, the innovative approach described in this report, are that the sensing probe can be easily adapted for inspection of different sizes of flanges and the costs for development and application of this technique will be very low. Significant conclusions from the research included: (1) the results fully demonstrated the feasibility of using the pulsed current resistance technique for the non-destructive detection of crevice corrosion in flanges; (2) resistance measurements based on current pulsing are more sensitive than measurements made using constant DC currents; (3) the pulsed current resistance measurement technique can be easily automated and computerized, which can provide high resolution three-dimensional images of flange damage. The key research and development area for follow-on work is full development of an automated, portable, flange crevice corrosion detection system, consisting of: (1) resistance probes of appropriate size; and (2) a computerized resistance meter based on high amplitude pulsed currents/low voltage sensing system. COLD EXPANSION AND INTERFERENCE FOR EXTENDING THE FATIGUE LIFE OF MULTI-LAYER METAL JOINTS
J. M. Finney Oct. 1993 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A274982; ARL-RR-17; DODA-AR-008-369) Avail: CASI HC A03

The influences of both hole cold expansion and interference-fit fasteners for extending the fatigue life of multilayer aluminum alloy joint specimens under variable amplitude loading have been examined experimentally. Improvements in fatigue life were markedly dependent on the degree of load transfer in the specimen joint. The cold expansion of fastener holes enhanced fatigue life in low load transfer joints but not in 100% load transfer joints. The use of interference-fit fasteners, especially at high degrees of interference, was an effective means of life improvement irrespective of proportion of load transfer. Interfacial fretting limited the improvement in fatigue life of low load transfer joints to a factor of about six, and, although some fretting occurred in 100% load transfer joints, it was not determinative, and a 40-fold increase in fatigue life was obtained with a combination of hole cold expansion and interference-fit fastener. TURBOMACHINERY FORCED RESPONSE PREDICTION SYSTEM (FREPS): USER'S MANUAL Final Report
M. R. Morel and D. V. Murthy Mar. 1994 115 p
(Contract NAS3-25266; NAG3-1669; RTOP 505-63-5B; RTOP 232-01-0B)
(NASA-CR-194465; E-8518; NAS 1.26:194465) Avail: CASI HC A06/MF A02

The turbomachinery forced response prediction system (FREPS), version 1.2, is capable of predicting the aeroelastic behavior of axial-flow turbomachinery blades. This document is meant to serve as a guide in the use of the FREPS code with specific emphasis on its use at NASA Lewis Research Center (LeRC). A detailed explanation of the aeroelastic analysis and its development is beyond the scope of this document, and may be found in the references. FREPS has been developed by the NASA LeRC Structural Dynamics Branch. The manual is divided into three major parts: an introduction, the preparation of input, and the procedure to execute FREPS. Part 1 includes a brief background on the necessity of FREPS, a description of the FREPS system, the steps needed to be taken before FREPS is executed, an example input file with instructions, presentation of the geometric conventions used, and the input/output files employed and produced by FREPS. Part 2 contains a detailed description of the command names needed to create the primary input file that is required to execute the FREPS code. Also, Part 2 has an example data file to aid the user in creating their own input files. Part 3 explains the procedures required to execute the FREPS code on the Cray Y-MP, a computer system available at the NASA LeRC. Derived from text

MODELLING AND ANALYSIS OF CREEP DEFORMATION AND FRACTURE IN A 1 Cr 1/2 Mo FERRITIC STEEL
B. F. Dyson and D. Osgerby 1993 47 p
(PB94-138328; NPL-DMM(A)-116) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

A quantitative model, based upon a proposed new mechanism of creep deformation in particle-hardened alloys, has been validated by analysis of creep data from a 13CrMo 4 4 (1Cr 1/2 Mo) material tested under a range of stresses and temperatures. The methodology that has been used to extract the model parameters quantifies, as a first approximation, only the main degradation (damage) processes - in the case of the 1CR 1/2 Mo steel, these are considered to be the parallel operation of particle-coarsening and a progressively increasing stress due to a constant-load boundary condition. These 'global' model parameters can then be modified (only slightly) as required to obtain a detailed description and 'fit' to the rupture lifetime and strain/time trajectory of any individual test. The global model parameter approach may be thought of as predicting average behavior and the detailed fits as taking account of uncertainties (scatter) due to variability in the material. Using the global parameter dataset, predictions have also been made of behavior under biaxial stressing; constant straining rate; constant total strain (stress relaxation) and the likely success or otherwise of metallographic and mechanical remanent lifetime procedures. A METHOD FOR THE PROBABILISTIC DESIGN ASSESSMENT OF COMPOSITE STRUCTURES
Michael C. Shiao (Sverdrup Technology, Inc., Brook Park, OH.), Surendra N. Singhal (Sverdrup Technology, Inc., Brook Park, OH.), and Christos C. Chamis Mar. 1994 16 p Presented at the 24th International SAMPE Technical Conference, Toronto, Ontario, 20-22 Oct. 1992; sponsored by the Society for the Advancement of Materials and Process Engineering
(RTOP 510-02-12)
(NASA-TM-106384; E-8204; NAS 1.15:106384) Avail: CASI HC A03/MF A01

A formal procedure for the probabilistic design assessment of a composite structure is described. The uncertainties in all aspects of a composite structure (constituent material properties, fabrication variables, structural geometry, service environments, etc.), which result in the uncertain behavior in the composite structural responses, are included in the assessment. The probabilistic assessment consists of design criteria, modeling of composite structures and uncertainties, simulation methods, and the decision making process. A sample case is presented to illustrate the formal procedure and to demonstrate that composite structural designs can be probabilistically assessed with accuracy and efficiency. Author (revised)

STIFFNESS-GENERATED RIGID-BODY MODE SHAPES FOR LANCZOS EIGENSOLUTION WITH SUPORT DOF BY WAY OF A MSC/NASTRAN DMAP ALTER
Ayman A. Abdallah (Analex Corp., Brook Park, OH.), Alan R. Barnett (Analex Corp., Brook Park, OH.), Timothy W. Widrick (Analex Corp., Brook Park, OH.), Richard T. Manella, and Robert P. Miller Mar. 1994 18 p Proposed for presentation at the 1994 MSC World Users' Conference, Orlando, FL, 20-24 Jun. 1994; sponsored by the MacNeal-Schwendler Corp.
(Contract NAS3-25776)
(NASA-TM-106537; E-8676; NAS 1.15:106537) Avail: CASI HC A03/MF A01

When using all MSC/NASTRAN eigensolution methods except Lanczos, the analyst can replace the coupled system rigid-body modes calculated within DMAP module READ with mass orthogonalized and normalized rigid-body modes generated from the system stiffness. This option is invoked by defining MSC/NASTRAN r-set degrees of freedom via the SUPORT bulk data card. The newly calculated modes are required if the rigid-body modes calculated by the eigensolver are not 'clean' due to numerical roundoffs in the solution. When performing transient structural dynamic load analysis, the numerical roundoffs can result in inaccurate rigid-body accelerations which affect steady-state responses. Unfortunately, when using the Lanczos method and defining r-set degrees of freedom, the rigid-body modes calculated within DMAP module REIGL are retained. To overcome this limitation and to allow MSC/NASTRAN to handle SUPORT degrees of freedom identically for all eigensolvers, a DMAP Alter has been written which replaces Lanczos-calculated rigid-body modes with stiffness-generated rigid-body modes. The newly generated rigid-body modes are normalized with respect to the system mass and orthogonalized using the Gram-Schmidt technique. This algorithm has been implemented as an enhancement to an existing coupled loads methodology. Author (revised)

NUMERICAL ANALYSIS OF DYNAMIC DIRECT TENSION AND DIRECT COMPRESSION TESTS Final Report, Feb. 1990 - Apr. 1991
Joseph W. Tedesco, Mary L. Hughes, and Brian P. ONeil Jan. 1993 379 p
(AD-A275255; AFCESA/ESL-TR-91-41) Avail: CASI HC A17/MF A03

This report summarizes the results of a comprehensive numerical analysis of direct tension and direct compression tests of plain concrete performed at strain rates between 1 and 10 to the 2nd power on a Split Hopkinson Pressure Bar (SHPB). The objective of this study was to investigate failure mechanisms in plain concrete specimens at high strain rates. Both an elastic and inelastic concrete material model were employed in all numerical analyses. The modes of failure predicted by the numerical analyses are consistent with those observed in experimental studies. In all instances, the mode of failure was significantly influenced by the rate of loading. DTIC

Many methods have been developed to aid analysts in identifying component modes which contribute significantly to component responses. These modes, typically targeted for dynamic model correlation via a modal survey, are known as target modes. Most methods used to identify target modes are based on component global dynamic behavior. It is sometimes

unclear if these methods identify all modes contributing to responses important to the analyst. These responses are usually those in areas of hardware design concerns. One method used to check the completeness of target mode sets and identify modes contributing significantly to important component responses is mode participation. With this method, the participation of component modes in dynamic responses is quantified. Those modes which have high participation are likely modal survey target modes. Mode participation is most beneficial when it is used with responses from analyses simulating actual flight events. For spacecraft, these responses are generated via a structural dynamic coupled loads analysis. Using MSC/NASTRAN DMAP, a method has been developed for calculating mode participation based on transient coupled loads analysis results. The algorithm has been implemented to be compatible with an existing coupled loads methodology and has been used successfully to develop a set of modal survey target modes. Author

MODELLING SOFT IMPACTS FOR VIBRATIONAL EXCITATION OF CIVIL ENGINEERING STRUCTURES
L. Agardh 1993 50 p
(PB94-137619; SP-RAPP-1993:50) Avail: CASI HC A03/MF A01

Experimental modal analyses of civil engineering structures are performed for various reasons. One is to assess the condition of the structure. Another is to verify the behavior of the structure under dynamic loads. An accurate method to excitate the structure is to use vibrators and random noise. For large structures in field conditions this may be quite expensive, and requires heavy equipment. Excitation by impact is often an effective alternative. In the report an impact equipment consisting of a striker and a mobile 'lift and drop' arrangement is used and some problems with impact excitation are discussed. The striker consists of a falling weight, a damper and a load cell. A soft interface between the load cell and the surface of the structure is used to prolong the contact time and filter out high frequency components. The contact force history is measured for 'soft' impacts on a stiff floor, for various choices of the mass and initial velocity of the striker. The floor is considered to be at rest during the impact event. Under these assumptions an analytical model of the contact force history is fitted to the measurements and used to solve a differential equation governing the striker system. From the solution the nonlinear stiffness of the striker system is estimated. NTIS

FINITE ELEMENT ANALYSIS OF AXISYMMETRIC DEFORMATIONS OF THICK THERMOVISCOPLASTIC TARGETS Ph.D. Thesis
Xingju Chen 1993 175 p
Avail: Univ. Microfilms Order No. DA9326587

The dissertation consists of four parts. We first conduct an approximate analysis of steady state axisymmetric deformations of a viscoplastic target being penetrated by a hemispherical nosed rigid penetrator. A kinematically admissible velocity field is presumed, and the unknown parameters are determined by minimizing the error in satisfying the balance of linear momentum. The solution so obtained is found to be very close to the finite element solution of the problem. In the second part, we postulate a velocity dependent expression for the frictional force on the target/penetrator interface. The values of the two constants in the expression for the frictional force are determined by comparing the distribution of the tangential traction on the penetrator nose surface as obtained from a finite element solution of the problem with that obtained by modeling the target material as a viscous fluid. The computed results show that the frictional force affects noticeably the tangential speed and the strain-rate on the penetrator nose surface, but minimally the normal traction there. Finally, we simulate numerically the penetration of a hemispherical nosed rigid rod into a thick thermoviscoplastic target and employ the aforestated expression for the frictional force. The finite element mesh is refined adaptively whenever one of its elements has been severely distorted. The computed results reveal that depth of penetration correlates well with the test value, the consideration of thermal softening of the target material influences strongly its deformations and the frictional force at the target/penetrator interface reduces the penetration depth by about 12 percent. ANALYSES OF STATIONARY AND GROWING CRACK TIP DEFORMATION BY DIGITAL IMAGE PROCESSING Ph.D. Thesis
Gang Han 1993 173 p
Avail: Univ. Microfilms Order No. DA9321959

Computer vision technique was applied to study crack tip deformation for a stationary crack and a stable growing crack in single edge cracked (SEC) specimens made by elastic and elastic-plastic material. The in-plane displacement and strain distributions in the vicinity of the crack tip before and after the crack initiation were obtained and compared with theoretical predictions. Results indicate that (1) the HRR solution can be used to quantify deformation field only in the region plastic strain strongly dominates the elastic strain, (2) for elastic-plastic materials, U has neither a elastic nor HRR singularity, V agrees with the HRR prediction in a large region. This suggests that higher order terms will be needed to accurately predict the deformation, (3) after the crack initiation crack tip deformation fields are controlled by J when w factor was smaller than 10.0, and (4) for small amounts of crack growth, the crack tip deformation fields seem to confirm the Quasi-static growing crack tip fields, predicted by the Gao-Hwang theory. In addition, the elastic unloading phenomenon for a growing crack was also investigated. In order to study the crack initiation and stable growth, the J-integral, crack tip opening displacement (CTOD) and crack tip opening angle (CTOA) were investigated to determine if they can be used as fracture parameters for thin specimens. Results indicate that the J resistance (J(sub R)), CTOD resistance and CTOA resistance curves were found to be independent of specimen size and a/w ratios; and CTOA are attained constant value when crack growth is larger than specimen thickness. However, the results for J-integral are dependent on the loading conditions. It was determined that J-integral value obtained of using displacement controlled condition was significantly lower relative to a load controlled condition for single edge cracked specimens having longer crack.

THE IMPACT OF ELECTRICALLY CHARGED MICROSPHERES WITH PLANAR SURFACES UNDER VACUUM CONDITIONS Ph.D. Thesis
Michael Joseph Caylor 1993 166 p
Avail: Univ. Microfilms Order No. DA9325913

The normal and oblique impact of electrically charged microspheres with planar surfaces under vacuum conditions is examined experimentally. The experimental methods and results are presented. An analytical model for the normal impact case is used to examine the empirical results. The impact experiments were performed in a vacuum test cell maintained at pressures near 1 x 10(exp -4) Torr. Three types of microspheres (approximately 1 to 50 microns diameter) were used including silver-coated glass, stainless steel and nickel. The particles were impacted against a set of five planar, target surfaces including three metallic surfaces, a polymer surface and a glass-coated surface. The particles were electrostatically charged by induction (from approximately 0.1 to 10 fC) and dispensed using an electrostatic particle dispenser. The particle velocities were controlled to provide the desired range of incident velocities (approximately 1 to 20 m/s). A one-component Phase Doppler Particle Analyzer (PDPA), which also provided a particle sizing capability, was used to measure incident and rebound velocities for the normal impact experiments. A particle trajectory imaging system (PTIS) was developed and used for velocity measurements for the oblique impact tests. Average particle electrostatic charge was determined using a charge sensitive amplifier and from electrometer current measurements. This unique experimental approach permitted the examination of individual impact events. The coefficient of restitution, e, was determined by a matching algorithm that paired corresponding incident and rebound velocities. Average values of e ranged from 0.45 to 0.85. The data demonstrated the presence of adhesion effects at low incident velocities (below 2 m/s). An analytical model of this type of impact process showed that the magnitude of van der Waals force was dependent on the amount of elastic deformation during impact. For the particle charge levels of approximately 0.5 fC, the contribution of the electrostatic image force to the total adhesion force was found to be negligible. Electron micrographs of the impact surface verified the occurrence of permanent deformation for some microsphere impacts. Impulse ratios, mu, determined from oblique impact tests also showed that the microspheres can not be considered as point masses in these impact experiments.

MECHANISMS AND EFFECTS OF HEAT GENERATION AT THE TIPS OF DYNAMIC CRACKS AND NOTCHES IN METALS Ph.D. Thesis
James Joseph Mason 1993 168 p
Avail: Univ. Microfilms Order No. DA9325369

It is known that plastic work in metals is converted mostly to heat. Under dynamic plastic deformation conditions there is not enough time for conductive, convective or radiative cooling to prevent the generated heat from raising the temperature of the material. The resulting temperature rise can significantly alter the material properties and influence the failure behavior of the material. Several experiments have been performed using a high speed InSb infrared (IR) detector array to examine the mechanisms and effects of heat generation at the tip of a dynamic notch or crack. First, dynamically propagating cracks are investigated. It is seen that adiabatic conditions exist at the crack tip resulting in a simple relationship between the active plastic work zone and the temperature field and that, consequently, no effects of hyperbolic heat condition are observed. The dependence of the dynamically propagating crack tip temperature field upon crack speed and material parameters is reported. Next, the dependence of the rate of conversion of plastic work to heat upon strain and strain rate are examined. Using the split Hopkinson bar several materials were tested and compared to simple theories in the literature. It is seen that the materials do not always behave as expected, and that further investigation is necessary. Last, asymmetrically impact loaded, stationary notches are investigated with special attention paid to the formation of adiabatic shear bands at the notch tip. A new interferometer, the coherent gradient sensor (CGS), is used in conjunction with high speed photography to record the deformation field around the crack tip. The recorded field is shown to agree with a model of the deformation for low velocity impact of PMMA. For high velocity impact of C300 steel, shear bands are formed and a Dugdale model is used to produce measurements of the shear stress on the shear band from the recorded fringe patterns. Dissert. Abstr.

ON FATIGUE CRACK CLOSURE: ANALYSIS AND MEASUREMENT Ph.D. Thesis
Majid Mirzaei 1991 195 p
(ISBN-0-315-74873-7) Avail: Univ. Microfilms Order No. DANN74873

This thesis describes a novel approach to the analysis of fatigue crack closure phenomena. Based on the proposed model, the combined effect of residual plastic stretch, asperity mismatch, and corrosion debris on the closure behavior of a fatigue crack can be simulated by a hypothetical rigid insert located in an ideal crack wake. Accordingly, the crack closing period can be modeled by a gradual contact between the ideal crack faces and the rigid insert. The formulation of the model results in a set of equations which can predict the closure load as well as the load-CMOD characteristics using the residual CMOD at zero load as a unique experimental input. Based on the initial model, the final form of the derived equations are either logarithmic or quadratic. While the latter can be solved directly for the closure load, the former requires a numerical solution. The model qualitatively predicts the effect of gradual crack wake removal on the crack closure load level and the load-CMOD behavior. It also accounts for the response of a cracked component to an anomalous crack wake formed by single or block overloads. The model is verified, both qualitatively and quantitatively, using specifically designed experimental techniques, a variety of specimen sizes, and two different alloys. Dissert. Abstr.

HIGHER ORDER ASYMPTOTIC CRACK TIP FIELDS IN A POWER-LAW HARDENING MATERIAL Ph.D. Thesis
Shaorui Yang 1993 102 p
Avail: Univ. Microfilms Order No. DA9322011

In this work, a method for determining a series of the higher order terms in the asymptotic expansion of the elastic-plastic crack-tip fields is developed. Based on the small strain formulation and the J(sub 2) deformation plasticity theory with power-law hardening, the governing equations for the higher order terms, which include the second, third and fourth order terms, are derived for both mode I and mode II loadings under either plane strain or plane stress conditions. Solutions for several higher order terms are presented. A comparison of the asymptotic expansion to finite element results indicates that the expansion can accurately predict the stress distribution for all angles within a substantial distance from the crack tip. For the mode I plane strain crack problem, it is found that, for the values of the hardening exponent n greater than or equal to 4 the four-terms asymptotic expansion with three independent amplitudes is controlled by plasticity; when n is greater than or equal to 3, the three-term expansion with two independent amplitudes is controlled by plasticity, and can be characterized by J and a second parameter A(sub 2) which is the dimensionless amplitude of the second order term. The effect of elasticity enters the second term at n = 1.5, the third term at n = 2, and the fourth term at n = 3. It is further demonstrated that the three-term expansion controlled by two parameters (J and A(sub 2)) can be used to describe the elastic-plastic crack-tip stress fields over a microscopically significant scale (1 less than (r-bar)/(J/sigma(sub o)) less than 5) for a variety of plane strain specimens at small to large scale yielding. The value of A(sub 2) can directly predict the stress triaxiality and the effect of geometry. It should be noted that, in general, the two-term expansion is not enough to predict the crack-tip field over the scale, because the effect of the third order term can not be neglected over the scale. For mode II case, two parameters (J and another parameter) control at least the first three terms for n less than or equal to 10 for both plane strain and plane stress problems. Dissert. Abstr.

Computer hardware and numerical analysis algorithms have progressed to a point where many engineering organizations and universities can perform nonlinear analyses on a routine basis. Though much remains to be done in terms of advancement of nonlinear analysis techniques and characterization on nonlinear material constitutive behavior, the technology exists today to perform useful nonlinear analysis for many structural systems. In the current paper, a survey on nonlinear analysis technologies developed and employed for many years on programmatic defense work at the Lawrence Livermore National Laboratory is provided, and ongoing nonlinear numerical simulation projects relevant to the civil engineering field are described. THEORETICAL PREDICTION OF THE INFLUENCE COEFFICIENTS ON DAMPED SIMPLE FLEXIBLE ROTORS USING THE TRANSFER MATRIX METHOD
Oh-Sung Jun (Korea Research Inst. of Standards and Science, Taejon, Republic of Korea.) and Paul Y. Kim Feb. 1994 60 p
(IMR-TM-TR-002; CTN-94-61133) Avail: CASI HC A04/MF A01

The influence coefficients for undamped flexible rotors are analytically derived and then compared and discussed for various damping coefficients. The concept of the transfer matrix method is partially adapted in the formulation. Single-disk and single cylinder rotor models are used for one- and two-plane balancing models, respectively. The gyroscopic effect of the disk or cylinder, which has been included in the formulation, is proved important through a simplified example rotor model. Taking the gyroscopic effect into account when calculating the influence coefficient is especially important near the resonant and antiresonant frequencies of the rotor. The simplified model also shows that an increase in damping reduces the sharpness of magnitude curve of influence coefficients and smoothens the change of phase at around the resonant and antiresonant frequencies.

POSITION CONTROL OF A FLEXIBLE BEAM WITH ACTIVE DAMPING OF VIBRATIONS M.S. Thesis [REGLAGE DE POSITION D'UNE POUTRE FLEXIBLE AVEC AMORTISSEMENT ACTIF DES VIBRATIONS]
Jean De Carufel 1992 166 p In FRENCH
(ISBN-0-315-85841-9; CTN-94-61169) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

A theoretical and experimental study was conducted on the active

damping of vibrations in a flexible beam having one free end and the other attached to the axis of a motor. Two methods for controlling the position of flexible structures are studied and are applied to the Euler-Bernoulli beam. The first is an active impedance dynamic gain method in the frequency domain. The second is a more complex method of feedback control by filtered states. A transfer function and a state model are also presented. The experimental work was conducted using a flexible beam, a direct current motor, and a digital controller. The experimental results were used to establish numerical models used for synthesizing the proposed controllers and for simulating the performance of these controllers. A good agreement was observed between the analytically evaluated natural frequencies and those obtained experimentally. Simulation and experimental results of application of the proposed control methods show that the active impedance dynamic gain method is advantageous for flexible structures of great modal complexity. ESTIMATION OF WEIBULL MODULUS FROM DYNAMIC AND STATIC FATIGUE EXPERIMENTS

M. J. Reece, J. M. Cox, R. Morrell, and M. R. Phillips Mar. 1993 29 p
(PB94-138641; NPL-DMM(A)-108) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In the statistical analysis of strength data on brittle materials, it is useful to estimate the range of uncertainties in the calculation of parameters which characterize strength distributions, such that the reliability of subsequent use of the parameters can be judged. This has been performed for simple short-term strength distributions before, but in this report we develop a method for analyzing static and dynamic fatigue data and evaluate it using a Monte Carlo simulation based on a single Weibull distribution of flaw sizes and hence inert strengths. It is shown that the technique is appropriate for analyzing 50 dynamic fatigue results over four decades of stressing rate, and gives a Weibull modulus with a confidence level similar to that for a randomly chosen set of simple strength test specimens. Similar results were obtained with an analysis of static fatigue tests. The method was applied to real experimental data for soda-lime glass and provided a reasonable match between the Weibull modulus for conventional strength testing and those for static and dynamic fatigue. ROOT-SUM-SQUARE STRUCTURAL STRENGTH VERIFICATION APPROACH

Henry M. Lee Apr. 1994 48 p
(NASA-TM-108453; NAS 1.15:108453) Avail: CASI HC A03/MF A01

Utilizing a proposed fixture design or some variation thereof, this report presents a verification approach to strength test space flight payload components, electronics boxes, mechanisms, lines, fittings, etc., which traditionally do not lend themselves to classical static loading. The fixture, through use of ordered Euler rotation angles derived herein, can be mounted on existing vibration shakers and can provide an innovative method of applying single axis flight load vectors. The versatile fixture effectively loads protoflight or prototype components in all three axes simultaneously by use of a sinusoidal burst of desired magnitude at less than one-third the first resonant frequency. Cost savings along with improved hardware confidence are shown. The end product is an efficient way to verify experiment hardware for both random vibration and strength. Author (revised)

THE ROLE OF PLASTIC DEFORMATION IN BRITTLE AND NEAR-BRITTLE CRACKING BEHAVIOR Ph.D. Thesis

Hyungjae Shin 1992 186 p
Avail: Univ. Microfilms Order No. DA9315726

New measurements are reported for the ambient temperature indentation behavior of silicon crystals, involving several types of indentation systems and indenter shapes. Analysis of these and previously reported measurements on either a force-indentation of size related ductile-brittle transition description or a hardness stress-strain basis leads to the conclusion that crack initiation in silicon is facilitated by Cottrell-type dislocation reactions. The occurrence of an undetected phase transformation is concluded to be, at most, a secondary factor. Nanoindentation test results obtained at the National Institute of Standards and Technology on carbon-ion implanted silicon material, produced at the Naval Research Laboratory, show that hardening of the silicon surface layer has occurred, particularly for the case of SiC being formed by high temperature implantation. Measurement of the orientations of (100) cleavage facets, presumably initiated by the Cottrell dislocation reaction mechanism, on split and transverse fractured steel materials has led to an interpreted influence of polycrystal texture on the ductile-brittle transition properties of the material. Dissert. Abstr.

CLOSED FORM EXPRESSIONS FOR A CONSISTENT STRESS MATERIAL NONLINEAR FINITE ELEMENT Ph.D. Thesis

Richard Lee Knipe 1993 101 p
Avail: Univ. Microfilms Order No. DA9328489

Finite element expressions for two dimensional elasto-plasticity problems were implemented in closed form. These closed form expressions are based upon a distribution of the elasto-plastic constitutive relationship that is consistent with the interpolating functions used for the displacement. Closed form expressions for the element tangent stiffness matrix and initial stress nodal load vector were developed for the non hierarchic constant, linear, and quadratic strain triangle. Decreased solution times were obtained when using the closed form expressions instead of expressions based on numerical integration. The quality of the solutions obtained from the closed form expressions was measured against published solutions for two dimensional elasto-plasticity problems. Dissert. Abstr.

PLANE STRAIN FINITE ELEMENT ANALYSIS OF SHEET FORMING OPERATIONS INCLUDING BENDING EFFECTS Ph.D. Thesis

Uk Youn Cho 1993 191 p
Avail: Univ. Microfilms Order No. DA9325477

An improved finite element method suitable for the plane-strain analysis of sheet metal forming operations is presented. The method incorporates a computationally efficient shell model and a consistent frictional contact algorithm through an implicit updated Lagrangian formulation. The workpiece material model is rigid-viscoplastic with a choice of power law hardening and plastic normal anisotropy and is capable of modeling a wide variety of sheet metals. A simplified nonlinear incremental shell theory is employed along with an optional reduced integration through the thickness for computational efficiency, while retaining the advantages of the kinematic model containing the bending effects. Complex tool geometry can be handled by discrete data points, by primitives (lines and arcs), or by analytical functions. The capabilities of the method are demonstrated through verification problems and comparisons with experimental data, benchmark results, and published data for several practical problems of the sheet metal forming industry. The problems include stretching and/or deep drawing operations, simulation of automobile panel section, and brake bending operation. As an independent investigation from the first portion of the dissertation, measured data from a set of simple bending experiments of two types of aluminum are presented and analyzed. Generated data from the experiments include strain histories (loading and unloading), spring back information (spring back angle and strains), and friction coefficients. As a by-product, a simple way of estimating the friction coefficient (Coulomb's law) during a bending operation is proposed and demonstrated. Dissert. Abstr.

A program to develop and evaluate fracture methodologies for the assessment of crack-tip constraint effects on fracture toughness of reactor pressure vessel (RPV) steels has been initiated in the Heavy-Section Steel Technology (HSST) Program. The focus of studies described herein is on the evaluation of a micromechanical scaling model based on critical stressed volumes for quantifying crack-tip constraint through applications to experimental data. Data were utilized from single-edge notch bend (SENB) specimens and HSST-developed cruciform beam specimens that were tested in HSST shallow-crack and biaxial testing programs. Shallow-crack effects and far-field tensile out-of-plane biaxial loading have been identified as constraint issues that influence both fracture toughness and the extent of the toughness scatter band. Results from applications indicate that the micromechanical scaling model can be used successfully to interpret experimental data from the shallow- and deep-crack SENB specimen tests. When applied to the uniaxially and biaxially loaded cruciform specimens, the two methodologies showed some promising features, but also raised several questions concerning the interpretation of constraint conditions in the specimen based on near-tip stress fields. Crack-tip constraint analyses of the shallow-crack cruciform specimen subjected to uniaxial or biaxial loading conditions are shown to represent a significant challenge for these methodologies. Unresolved issues identified from these analyses require resolution as part of a validation process for biaxial loading applications.

DYNAMIC MODELING OF MULTIBODY FLEXIBLE STRUCTURES Ph.D. Thesis
Jiechi Xu 1993 336 p
Avail: Univ. Microfilms Order No. DA9321229

The dynamic modeling of a three dimensional, multibody, flexible, structural system with mutually coupled multicoordinates of unknown large overall rigid body motion is discussed. The study includes theory development and mathematical modeling, time integration numerical technique investigation, computer simulation and results, and experimental measurements and verification. The specific structure under consideration is characterized as an open loop system with spherical unconstrained chains capable of three dimensional rotation motion. The elastic deflections and rotations change the instantaneous body shape and energy level of each individual flexible member and consequently affect the rigid body motion of the system. In return, rigid body motion induces passive inertial forces resulting from tangential, centrifugal, and Coriolis accelerations and therefore influence the elastic deformation. In addition, an elastic-to-elastic coupling phenomenon, an effect of elastic deformation in succeeding links on the current link, is also involved during the motion of the system. All of these strongly nonlinear coupling terms are accounted for and are derived exactly in the dynamic modeling of the structure. The Lagrangian approach associated with a conventional stiffness finite element method is adopted in the derivation of the dynamic equations of motion and in the space discretization of the flexible members. Some hypotheses are made in the modeling of three dimensional elastic deformations using finite element analysis in order to reduce the total elastic degrees of freedom and to simplify the procedure of space discretization with only minor loss of exactness. A special numerical technique, a sequential implicit-explicit time integration method with predictor-corrector schemes, is developed to solve a second-order, nonlinear, ordinary differential equation system with time-varying coefficient matrices. The numerical algorithms are capable of handling the dynamic equation systems with inherent characteristics involving the variables of large overall nonlinear rigid body motion and the variables of small linear vibration. A general purpose computer code is developed with the implementation of the numerical technique presented in this work. Multiple finite elements of beam type are selected for each flexible member in order to increase accuracy where concerned. Extensive computer simulation of the dynamic response of the system is performed for several cases with different conditions and numerical parameters. The measurement instrumentation and computerized data acquisition system are set up to measure structural deflections at different locations. The most significant deformation, the overall deflection at the end of the chain accounting for all the possible elastic deflections and rotations preceding that location, is also calculated and the result is compared with experimental data. Good agreement between the analytical and experimental results in terms of overall radial deflection at the tank center is achieved. Dissert. Abstr.

AN INVESTIGATION OF FATIGUE CRACK PROPAGATION UNDER MODE 1 AND MIXED MODE 1/2 LOADINGS Ph.D. Thesis
Tapan Kumar Paul 1993 174 p
Avail: Univ. Microfilms Order No. DA9315794

An investigation on fatigue crack propagation under mode 1 and mixed mode (1 and 2) loadings has been performed. Fatigue crack growth data in the case of plane strain mode 1 have been obtained by performing experiments on compact tension specimens of 4340 steel for increasing Delta-K(sub 1), decreasing Delta-K(sub 1), and constant Delta-K(sub 1) loading conditions. Under mixed mode plane stress condition, the fatigue crack growth trajectory has been determined by performing experiments on the center cracked thin disk specimen of aluminum 2024. With two mixed mode loading ratios, the subsequent propagation of the main crack has been performed by producing a series of kinks and forks. For practical applications such as the case of a flaw or a crack in aircraft or ship structure in which the loading axis (with respect to the crack) frequently changes, a zig-zag or complicated crack trajectory is very important in both experimental and theoretical studies. In order to apply any specific crack growth criterion for the analysis of the experimental results, a detailed analysis for the stresses near the crack front and the extent of yielding is necessary. A full field solution, based on small deformation, three dimensional elastic-plastic finite element analysis of the centrally cracked thin disk under mode 1 loading has been performed. The solution for the stresses under small-scale yielding and locally fully plastic state has been compared with the HRR plane stress solution. At the outside of the three dimensional zone, within a distance of r sigma(sub 0)/J = 18, HRR dominance is maintained in the presence of a significant amount of compressive stress along the crack flanks. Ahead of this region, the HRR field overestimate the stresses. These results demonstrate a completely reversed state of stress in the near crack front compared to that in the plane strain case. The combined effect of geometry and finite thickness of the specimen on elastic-plastic crack tip stress field has been explored. Under mixed mode loading, the dominance of the elastic K-field outside the elastic-plastic region has been demonstrated at the load level at which the crack extension experiment has been performed in the thin disk. The complex crack trajectory has been analyzed on the basis of the strain energy density criterion for the prediction of propagated crack path under subsequent changes in orientation of the crack to the loading axis or, equivalently, the changes in loading direction with respect to the crack. Dissert. Abstr.

SECOND-ORDER STRUCTURAL IDENTIFICATION VIA STATE SPACE-BASED SYSTEM REALIZATIONS Ph.D. Thesis
Kenneth F. Alvin 1993 216 p
Avail: Univ. Microfilms Order No. DA9320384

The present study has focused on the estimation of normal modes and their mode shapes from experimental data. The determination of accurate undamped modal parameters from experimental data in the presence of damping is critical for the construction or reconciliation of structural dynamics models, in which the physical mass and stiffness properties are isolated from the dissipative effects of damping. The response functions measured from experimental data are generally approximated by finite-dimensional first-order difference equations in the time domain using algorithms such as ERA. Such models, or realizations, do not directly determine the mass and stiffness matrices, except under special restrictions. This thesis develops a family of transformation-based methods for the construction of second-order structural dynamic models from first-order system realizations of experimental data. Transformations to a second-order canonical basis are effective for the systematic extraction of the normal modes from the first-order realizations. Two separate transformations are developed: the common basis normalized structural identification (CBSI)

procedure and the uncoupled nonproportional damping (UNDAMP) procedure. CBSI transforms the first-order state space realizations to the well-known form of second-order proportionally damped equations of motion. The resulting structural dynamics models are shown not only to yield the accurate normal modes for proportionally damped cases, but also improved estimates of the normal mode shapes in the presence of nonproportional damping as compared to existing methods. The UNDAMP algorithm extends the CBSI method to a global transformation spanning up to the full space of the damped modes. As such, UNDAMP is capable of filtering out the contaminating attributes of nonproportional damping from the CBSI-determined normal modal parameters. Furthermore, UNDAMP is applicable to the extracting of nonproportional damping when the number of measured sensors is less than the number of identified modes. Using normal modal parameters determined by CBSI or UNDAMP a method for determining minimal-order mass and stiffness matrices is presented. The resultant model is an alternative second-order realization with measured physical variables as degrees of freedom, and the derived mass and stiffness matrices are shown to have asymptotic equivalence to Guyan-reduced and/or Craig-Bampton synthesized structural models. The efficiency and accuracy of the present transformation methods are demonstrated through simulated numerical examples and experimental data. In particular, the present methods are used to reconstruct frequency response functions and applied to damage detection in truss structures. Finally, the implications of these analytical techniques for structural system identification and directions for future research are also discussed. Dissert. Abstr.

WISPER AND WISPERX: FINAL DEFINITION OF TWO STANDARDISED FATIGUE LOADING SEQUENCES FOR WIND TURBINE BLADES
A. A. tenHave 23 Sep. 1992 84 p Sponsored by Netherlands Agency for Energy and Environment Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B175835; NLR-TP-91476-U; ETN-94-95569) Avail: CASI HC A05

Relevant information used to develop WISPER (Wind turbine reference Spectrum) and WISPERX, standardized variable amplitude test loading histories for use in the fatigue design of horizontal axis wind turbine blades, is presented. WISPER and WISPERX are based on flap load service measurements on nine different horizontal axis wind turbines, covering a wide range of materials, rotor diameters and geographical locations. Their backgrounds are reported, basic data and associated data handling procedures are described, and quantitative data analysis results and statistical information on both standards are presented. The information given will enable fatigue specialists to judge whether the standard will suit their test objectives and to check for correct application of the load sequences on their test equipment. THIN-WALLED ORTHOTROPIC LAMINATED BEAM THEORY Ph.D. Thesis
Gerry Darren Pollock 1993 164 p
Avail: Univ. Microfilms Order No. DA9329139

A refined beam theory is developed for thin-walled, orthotropic, laminated elastic beams. The motivation for the formulation is the necessity of accounting for deformations brought about by coupling induced shear strains in open section beams. The engineering formulation allows for completely arbitrary section geometry and lay-ups. The present theory and a related closed section theory are validated by comparisons with experimental, finite element, and other analytical methods. The results show the necessity of incorporating shear strain produced deformations for open sections. In general, both the open section and closed section results agree to within 10 to 15 percent of either experimental or finite element data for a broad range of section geometries, lay-ups and loadings. The present open and closed section formulations reduce, as required, to their classical isotropic counterparts when isotropic properties are invoked. Shear center concepts for anisotropic beams are investigated as well. For arbitrary ply lay-ups, it is impossible to find a point (shear center) at which applied shear loads simultaneously satisfy conditions of zero twist and zero resultant moment. The method of determining isotropic shear centers leads to moment balancing of resultant shear load and shear stresses about some point. A completely analogous procedure can be arrived at for anisotropic beams, and hence the condition of zero resultant torque is deemed the more natural condition to satisfy. The consequence is that the beam twists despite the fact that the shear load passes through the shear center. Anisotropic shear centers are found to be functions of material properties. Dissert. Abstr.

THE JAPAN SEA PROPER WATER AND WATER CIRCULATION IN THE JAPAN SEA [NIHONKAI KOYUSUI NO SEISEI TO NIHONKAI NO KAISUI JUNKAN] **c48**
Katsunobu Nishiyama, Masaru Inagawa, and Takanori Mizuno *In its* Papers in Meteorology and Geophysics, Vol. 44, No. 1 31 Mar. 1993 p 1-10 (For primary document see N94-28693 08-42)
Avail: CASI HC A02/MF A01

Water circulation in the Sea of Japan is characterized as a formation of the Sea of Japan proper water from the data observed in 1969 by research vessels belonging to the Japan Meteorological Agency. Below 500 m depth in the Sea of Japan, salinity is relatively high in the northern part and low in the southern. This is opposite to the conditions in the surface layer, where the northern part is generally the cold current region and the southern part the warm current region. In the southern part of the eastern Japan Basin of the northern Sea of Japan anticyclonic circulation occurs and sea waters sink towards the bottom. In the western Japan Basin and in the Yamato Basin, sea waters flow upward, in contrast to the southern part of the eastern Japan Basin. Therefore, vertical water circulation generates in the deep layer of the Sea of Japan, that is, downwelling appears in the southern part of the eastern Japan Basin, and upwelling occurs in the western Japan Basin and in the Yamato Basin.

Verkley (1987, 1990) constructed modons on a sphere as models of atmospheric blocking phenomena. These are exact solitary wave solutions to the barotropic potential vorticity equation on a sphere. In this report, the linear Liapunov stability of Verkley's 1987 modons is proved by means of Arnol'd's invariant, and moreover it is shown that Verkley's 1990 modons are linearly spectrally stable. In spite of the fact that Arnol'd's invariant

does not exist for the 1990 modon, it is still possible for the 1990 modon to be proved linearly spectrally stable because of the fact that the 1990 modon is a limiting case of the 1987 modon. Author (NASDA)

STRUCTURE OF NEUTRALLY STRATIFIED TURBULENT EKMAN LAYER AS PREDICTED BY CLOSURE MODELS WITH PROGNOSTIC EQUATION FOR MASTER LENGTH SCALE **c46**
Nobuyuki Kinoshita *In its* Papers in Meteorology and Geophysics, Vol. 44, No. 1 31 Mar. 1993 p 17-28 (For primary document see N94-28693 08-42)
Avail: CASI HC A03/MF A01

The turbulent Ekman boundary layer in a neutral atmosphere is studied by means of a second order turbulence closure model incorporated with a prognostic equation for the master length scale and those of a one-and-a-half order closure model. The results of the second order closure model are compared with those of a second order closure model incorporated with an equation for the dissipation rate, an E-epsilon model and a direct numerical simulation. It is shown that the height of the Ekman layer simulated by the present model is higher than those by the other closure models and that the turbulence kinetic energy and turbulent momentum fluxes in the upper part of the boundary layer are larger. These differences result from the fact that the length scale predicted by the present model is longer than those by the other closure models. The structure of the Ekman boundary layer simulated by the present second order closure model is close to that by a direct numerical simulation. The results of the one-and-a-half order closure model coincide with the present results, though it is found that the growth of the boundary layer is a little slower than that of the present second order closure model. EXPLOITATION OF STEREOPHOTOGRAMMETRICALLY DERIVED 3-D WIREFRAME MODELS TO PRODUCE URBAN SIMULATIONS Scientific Paper
Tom Witte Feb. 1994 7 p
(AD-A275459; TEC-R-214) Avail: CASI HC A02/MF A01

The U.S. Army Topographic Engineering Center (TEC) is investigating methods to incorporate photogrammetrically derived 3-D models of urban features into terrain visualization software, to facilitate the photorealistic simulation of urban environments. Ideally, cultural features such as buildings will be extracted automatically from digital imagery as 3-D wireframe models. Coordinates representing the vertices of the models are to be input to terrain visualization software running on a Unix workstation. Phototexture is to be applied to the models and to the underlying digital terrain elevation data in order to create photorealistic, 3-D urban environments for simulated fly-throughs. DTIC

THERMAL VARIATION IN VEGETATED OR SNOW-COVERED BACKGROUND SCENES AND ITS EFFECT ON PASSIVE INFRARED SYSTEMS
Lindamae Peck Nov. 1993 22 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 4A7-62784-AT-42)

The diurnal and seasonal variations in the magnitude of and rate of change of surface temperature were investigated for vegetated and snow-covered ground under winter, summer, and transitional weather conditions at a site in Vermont. The variability in thermal radiance is evident as changes in the proximity-to-alarm status of passive infrared detection systems. A midwinter snow cover is the most favorable background because its associated thermal radiance changes are less dynamic than are the radiance changes of uniform grass covers in summer or mixed backgrounds of grass, thatch, and soil following winter. Grass, thatch, and soil backgrounds typically experience a larger diurnal range in temperature (from nighttime low to daytime high) and greater spatial variability in thermal radiance than do the uniform grass covers. The summer grass is more likely to be long enough to blow in the wind, thereby causing a change in thermal radiance as variously the sun-warmed, upper portion of the grass blades or the shaded (and therefore cooler) basal portion of the grass blades, and perhaps the sheltered soil, are momentarily exposed to the passive infrared system. Observations during rain-on-snow indicate three evolutionary regimes of snow behavior, immediate avalanching, delayed avalanching, and a return to stability. Immediate avalanching occurs within minutes of the onset of rain. This is important information for avalanche control technicians; the avalanches release several hours before, liquid water has penetrated to the sliding layer. Delayed avalanches release several hours after rain has started. The delay varies depending on the rate of increasing stress associated with additional precipitation, and the time taken for water to penetrate and weaken the snowpack. Avalanche activity is rare after continuation of rain for 15 hours or more. This return to stability occurs after a drainage system has been established. Infiltration is not uniform and water penetrates through localized channels that often occupy less than 50% of the total volume of the snowpack. Runoff starts much sooner than would be predicted if wetting was homogeneous. In situ measurements of deformation indicate that the strain rate in low density snow often increases without increased normal loading. Forces other than gravity must contribute to the deformation. This important finding is supported by measurements on slopes that show that the usual assumption that snow behaves as a linear, isotropic, viscous material is incorrect. A new theory involving thermodynamically induced strain is suggested. DTIC

More importance has been placed nowadays on remote sensing, a new field ranging in many professional areas, while global environment issues are getting much public attention. In order to promote the development of various types of satellites for earth observation and their sensors, Japan should focus on the following: an organization must be established where basic studies and research and development on remote sensing can entirely be conducted; aircraft for remote sensing experiments and observations should be prepared for sensor development, data collection and accumulation by new sensors, and practical observations; and observation satellites should be continued in sequence - many of the satellites were not continued for the second or third versions, and thus continuous data are not available, inconveniencing data users. Although these three items cannot be achieved immediately, it is strongly hoped that Japan will grow in joining the advanced countries in the field of remote sensing satellites. Author (NASDA)

The future will see a major increase in the utilization of spaceborne imaging radars in earth sciences and applications. ERS-1 and ERS-2 as well as RADARSAT will provide extensive amounts of coverage and large scale monitoring. Imaging radars have been used for geologic mapping of planetary surfaces, mapping of surface morphologic texture and roughness, mapping or the polar ice cover and ocean surface features, and monitoring of land use changes. Future potential applications will capitalize on the ability of the radar signal to sense volumetric information and to measure surface moisture. Three new techniques have the potential for major advances in the field of spaceborne radar remote sensing: radar polarimetry, radar interferometry, and bistatic imaging. The power of the radar data will be significantly enhanced when the advanced capabilities using these three techniques become widely available and when the synergism of visible infrared and microwave system is fully exploited. Since 1989, a focused area study 'Exploration of Earth Environment by Satellites' funded by the Ministry of Education is ongoing as a three-year program. The objectives of the program is, by utilizing the information on earth observed from space, to establish observation techniques for various earth environments and to conduct basic researches so as to understand the mechanism of environmental changes, utilizing the information on earth observed from space. Understanding earth phenomena ranging in atmosphere, geosphere, and hydrosphere requires an earth observation technique by satellites allowing collection of information covering large areas in a short time as well as multiple observation of the same areas. Applications of this technique, remote sensing, are expected to see significant increase. Japan is still behind in the basic studies to utilize data from satellites to academic studies of global environments covering air, ocean and land. The program was established to cope with these problems with an intention to catch up with Europe and the USA. With close cooperation between scientists and engineers, this program aims for effective researches featuring boundary area studies between atmosphere and geosphere, atmosphere and hydrophere, and geosphere and hydrosphere, for example. Optical Sensor (OPS) and Synthetic Aperture Radar (SAR) simulation studies were made in 1989 and 1990 at test sites in the U.S. The main purpose was to jointly understand and develop applications of simulated Japanese Earth Resources Satellite-1 (JERS-1) electro-OPS and SAR remote sensing technology to petroleum and mineral geological mapping problems before the scheduled launch of the Japanese JERS-1 satellite in 1992. The studies at various sites demonstrated that the JERS-1 data would be superior to other satellite remote sensing data for many geologic mapping applications, and that the data could be expected to effectively map major rock and alteration types, and better discriminate between hydroxyl-bearing rocks. Moreover, the JERS-1 data will improve the mapping of subtle lithologic variations regionally within sedimentary sequences of rocks. These capabilities for better mineral, alteration, and rock facies discrimination will contribute significantly to geological remote sensing worldwide. The JERS-1 data will provide new and improved spectral information for mapping and understanding earth's land and ocean surfaces for global resource development and better global environmental management.

IMAGE PROCESSING FOR HYPERSPECTRAL DATA Abstract Only [CHO TABANDO DETA NO GAZO SHORI]
Andrew A. Green, M. Berman, and M. Craig *In* Earth Resources Satellite Data Analysis Center, Proceedings of the International Symposium on Remote Sensing 30 Mar. 1992 p 145-147 (For primary document see N94-28925 08-43)
Avail: CASI HC A01/MF A03

A number of methods, including expert system methods, were examined for the interpretation of very high dimensional remote sensing data. Many of them were thought to be too cumbersome for dealing with spectra which were a mixture of several components. Among these expert system methods, the most persuasive argument was the clear advantages of unmixing techniques, which seemed to be the best way to proceed in the analysis of high dimensional data sets. The main reason was that despite the very large number of bands acquired, the fundamental dimensionality of the data was usually much less. It became clear that the data variability is determined by the linear mixing of the radiance properties of relatively few spectally distinct materials, called endmembers. Inconveniences of principal components analysis led to the development of a new coordinate transformation which produces new components that separate the signal and noise as much as possible. It was found that band-to-band misregistration could cause serious problems in the unmixing process. Not only does it invalidate the assumptions made in the mixing model, it gives the data extra dimensionality by simulating false endmembers. The selection of endmembers in high dimensional data is difficult because of our weak capability to visualize the data distributions. Author (NASDA)

The Japanese Earth Resources Satellite-1 (JERS-1) system consists of a space segment (the satellite itself) and a ground segment. The satellite has two sections: a bus section with basic functions of communication data processing and power supply, and a mission section. The mission section includes the following: (1) Synthetic Aperture Radar (SAR) which provides means to obtain information of objects by measuring scattering coefficients; (2) an Optical Sensor (OPS) which gathers lights (both forward and directly below the satellite) to be filtered and converted later to electric signals; (3) a mission data transmitter which transmits SAR, OPS, and Mission Data Recorder (MDR) data to ground; and (4) a mission MDR which records, reproduces and outputs SAR and OPS data to ground stations. The ground segment consists of: (1) tracking and control functions; (2) data acquisition and processing functions responsible for data receiving, recording, processing, inspection, evaluation, storage, retrieval and distribution; and (3) Mission Management Organization (MMO) which coordinates various requests and transmits mission operation requests, operation plans and orbit information, and performs the primary evaluation of mission instruments. JERS-1 DATA AND INFORMATION SYSTEM FOR RESOURCES EXPLORATION [SHIGEN TANSA NO TAMENO JERS-1 KANSOKU DETA RIYO SHISUTEMU NI TSUITE]
In its Proceedings of the International Symposium on Remote Sensing 30 Mar. 1992 p 189-204 In ENGLISH and JAPANESE Original contains color illustrations (For primary document see N94-28925 08-43)
Avail: CASI HC A03/MF A03

The Japanese Earth Resources Satellite-1 (JERS-1), scheduled to be launched in February 1992, was jointly developed by the Ministry of International Trade and Industry (MITI) and the National Space Development Agency of Japan (NASDA). JERS-1 has two mission sensors: an L-band synthetic aperture radar, and an optical sensor which gathers reflected sunlight from the earth in the regions between visible, near infrared to short-wavelength infrared lights. JERS-1 has been getting much attention not only from those conducting resources exploration but also from various users both domestic and abroad for forestry, fishery, agriculture, and environmental management. The Earth Resources Satellite Data Analysis Center (ERSDAC) engages in promotion of research and development of remote sensing technologies, application to resources exploration, and collection of ground truth data. With guidance from the MITI and cooperation with relevant organizations, the ERSDAC has started to develop JERS-1 Data and Information System (ERSDIS) to effectively utilize observation data from JERS-1. The operation is expected to start in the middle of 1992, and international users will be accepted if conditions allow. The distribution policy of JERS-1 observation data is expected to be settled at the start of ERSDIS's operation at the latest. By taking users' advice and opinions into account, ERSDIS will be further improved and refined.

Avail: CASI HC A03/MF A03

The European Remote Sensing Program is designed as an end-to-end system to serve a large variety of users with a wide range of response-time and applications requirements. The first ERS (European Remote Sensing Satellite) mission, built around the launch of ERS-1, was expected to demonstrate the ability of remote sensing systems to provide valuable earth-observation data from space platforms. The performance of various sensors onboard ERS-1 (apart from the PRARE (Precise Range and Range Rate Experiment) instrument) has been very promising. All LBR (Low Bit Rate) sensors showed a behavior well beyond the more optimistic expectations. The wind scatterometer gave very good results, and the radar altimeter clearly showed its ability to generate the global wind and wave pattern fields in the ocean/atmosphere system. Both instruments will be extremely powerful tools for meteorologists. The SAR (Synthetic Aperture Radar) image revealed astonishing performance. The SAR showed an incredible amount of information extremely useful for several categories of scientists and applications studies including land processes monitoring, disaster accessment, and coastal and off-shore applications. The fast delivery processor showed results that were very promising for users that wish receive the data in near real time. Author (NASDA)

SEA ICE AND OCEANS APPLICATIONS OF SAR [SA NI YORU KAIYO KANSOKU] **c48**
Michael J. Manore, Paris W. Vachon, and Marie-Catherine Mouchot *In* Earth Resources Satellite Data Analysis Center, Proceedings of the International Symposium on Remote Sensing 30 Mar. 1992 p 247-271 Original contains color illustrations (For primary document see N94-28925 08-43)
Avail: CASI HC A03/MF A03

This paper will examine the use of remote sensing technologies, specifically Synthetic Aperture Radar (SAR), for sea ice and ocean applications. The emphasis on SAR is made because of the large volume of such data expected for the first time in the 1990's from a number of different satellite platforms (e.g., ERS-1, Japanese Earth Resources Satellite-1 (JERS-1), and RADARSAT). In addition, the all-weather capability of microwave sensors is particularly well suited to ice and oceans applications because the regions of interest are often affected by poor conditions for optical imaging (i.e., cloud, fog, darkness). Overall, SAR is an excellent sensor for ice applications because it is capable of distinguishing open water from ice and discriminating among different types of ice. This information is used operationally for ship navigation. For oceans applications, the technical complexity of imaging the moving ocean surface makes the reliable extraction of wave information difficult, especially from satellite sensors. However, SAR is capable of imaging oceanographic features such as current fronts, eddies, and large scale waves under low-wind conditions. The applications of SAR described in this paper will be highlighted with examples of recent Canadian activities. Author (NASDA)

AMAZONIA: REMOTE SENSING TEST SITE AND SURVEY [AMAZON NI OKERU SEIKATSUIKI NO KAKUDAI TO SHINRIN NO HOZEN]
Roberto PereiradaCunha *In* Earth Resources Satellite Data Analysis Center, Proceedings of the International Symposium on Remote Sensing 30 Mar. 1992 p 273 (For primary document see N94-28925 08-43)
Avail: CASI HC A01/MF A03

Microwave remote sensing has been a promising tool since early seventies when SAR (Synthetic Aperture Radar) airborne campaigns began worldwide. The nineties reached the microwave remote sensing satellite era: ERS-1; JERS-1 (Japanese Earth Resources Satellite-1); and RADARSAT. To a large extent, the user community has been exposed to isolated examples of application of microwave remote sensing for test areas. Now, the time has come when one has the opportunity to use the full coverage provided by systematically orbiting, microwave remote sensing satellites. Amazonia has been envisaged as a test site or calibration site for the last ten years, even though several other forested areas may serve for the same purposes. Today, in some cases, much of expertise needed is for the ability to work with very large areas where an enormous amount of data have to be handled. The paper and presentation will focus on recent studies done for deforestation evaluation of the Amazonia based on wall to wall satellite coverage. These studies previously done to the ERS-1 and JERS-1 will allow comparisons with SAR coverage. Other environmental issues such as mining will also be addressed. Author (NASDA)

UTILIZATION OF REMOTE SENSING DATA IN SOUTHEAST ASIA [TONAN AJIA NI OKERU RIMOTO SENSHINGU DETA NO RIYO]
Suvit Vibulsresth *In* Earth Resources Satellite Data Analysis Center, Proceedings of the International Symposium on Remote Sensing 30 Mar. 1992 p 275-291 Original contains color illustrations (For primary document see N94-28925 08-43)
Avail: CASI HC A01/MF A03

In Southeast Asia, the problems of soil erosion due to deforestation,

land degradation due to salt accumulation, and desertification are approaching an alarming scale. Most countries also depend on the export of natural resources. In the past the reserve and the distribution of natural resources in Southeast Asia had not been sufficiently mapped and the management of natural resources on a national scale had been deficient. By focusing on the synoptic, temporal and uniformity of satellite imagery, the countries in Southeast Asia can utilize the remote sensing data for better management of their natural resources. Some examples are shown to highlight the applications. The role of remote sensing in policy-making of natural resources development projects is clearly stated. In Southeast Asia, a feedback management system is strongly needed whereby the gaps between the management goal as determined by policy-makers and the actual situation are constantly monitored on a seasonal or annual basis by remote sensing and fed back to the decision-making process.

Avail: CASI HC A03/MF A03

Remote sensing is utilized in many fields. It is a very effective means for mineral explorations. In lithology, rocks can be discriminated by images in high resolution and spectral characteristics. Visual images from satellites are useful for environmental monitoring. The simultaneity and wide coverage of remote sensing are considered quite beneficial for obtaining single year's information of the whole country of Japan, for instance, to study its land utilization. Remote sensing can also be applied to archaeology to discover ruins. Satellites contribute to the protection against natural disasters such as hurricanes, floods, and fires, or even to the capture of illegal wood cutters. However, in Southeast Asia including Bangladesh, an organization is not yet established to utilize the data from remote sensing, which could reduce damages from disasters. In Japan, projects related to hardware like computers are quite generously funded by the government, but software-related funding such as data analysis and utilization is less than 1/500 of the funding for hardware, and this could result in satellites just orbiting for nothing. International cooperation is vital in selecting and effectively utilizing remote sensing data with limited manpower and budget. It is also important to continue remote sensing, and extract, organize and systematize abundant data available. Consensus and cooperation are the two key words for the future in remote sensing. SPECTRAL AND POLARIMETRIC ANALYSIS OF HYPERSPECTRAL DATA COLLECTED BY AN ACOUSTO-OPTIC TUNABLE FILTER SYSTEM M.S. Thesis
Melissa A. Sturgeon 23 Sep. 1993 148 p
(AD-A275076) Avail: CASI HC A07/MF A02

Analysis of data collected during a ground-based experiment of an acousto-optic tunable filter (AOTF) hyperspectral imaging system illustrates the utility of this technology for military applications. The unique ability of an AOTF system to simultaneously acquire two orthogonally polarized images allows both spectral and polarimetric characterization of targets. The data images selected for analysis contain camouflaged military equipment deployed in a desert background. After geometric and atmospheric correction, spectral analysis is accomplished using two different methods. Comparing images created by the difference between polarizations for each band provides the basis for polarimetric analysis of the data. An algorithm developed to combine the information provided by spectral and polarimetric analysis shows how features within a scene can be distinguished from the background. Results show that AOTF hyperspectral technology has potential to enhance current military intelligence collection capabilities. DTIC

CONCEPTUAL RADIOMETER DESIGN STUDIES FOR EARTH OBSERVATIONS FROM LOW EARTH ORBIT
Richard F. Harrington Apr. 1994 44 p
(Contract NAS1-18584; RTOP 233-01-03-22)
(NASA-CR-4588; NAS 1.26:4588) Avail: CASI HC A03/MF A01

A conceptual radiometer design study was performed to determine the optimum design approach for spaceborne radiometers in low Earth orbit. Radiometric system configurations which included total power radiometers, unbalanced Dicke radiometers, and balanced Dicke, or as known as noise injection, radiometers were studied. Radiometer receiver configurations which were analyzed included the direct detection radiometer receiver, the double sideband homodyne radiometer receiver, and the single sideband heterodyne radiometer receiver. Radiometer system performance was also studied. This included radiometric sensitivity analysis of the three different radiometer system configurations studied. Both external and internal calibration techniques were analyzed. An accuracy analysis with and without mismatch losses was performed. It was determined that the balanced Dicke radiometer system configuration with direct detection receivers and external calibrations was optimum where frequent calibration such as once per minute were not feasible. ROLE OF SATELLITE OBSERVATIONS OF SEA-SURFACE TEMPERATURE IN THE DETECTION OF GLOBAL CHANGE
M. R. Allen 28 Nov. 1993 51 p
(PB94-138120; RAL-93-095) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report presents the scientific case for the development of a 10-12 year data-set of consistent, accurate, global observations of sea surface temperature (SST) from the Along-Track Scanning Radiometer (ATSR) and its successors, the ATSR-2 and AATSR. The case focuses on the role such data will play in detecting and quantifying evidence for anthropogenic climatic change. Four key areas in which data from the ATSR series can play a useful role are identified. They are: providing high spatial and temporal resolution data for the validation of climate models; providing independent corroboration of in situ observations of SST; providing direct evidence of global changes taking place; and allowing the detection of global patterns of change extending into the Southern Hemisphere extra-tropical regions. MODEL-ORIENTED DATA ANALYSIS WITH APPLICATIONS TO LAKE AND SOIL WATER SIMULATION Ph.D. Thesis
J. Kettunen 5 Nov. 1993 99 p
(PB94-136942; ISBN-951-221762-7) Avail: CASI HC A05/MF A02

The general aim of all water resources modelling is to cover the broadest possible range of empirical facts with the smallest possible set of hypotheses. The study, which summarizes eight earlier publications, undertook to investigate practical techniques to attain the goal. The aims of the study were to develop methods for structural characterization, optimal observational design and for choice of the best model structure from among rival candidates. The problems were analyzed using the theory of optimal experimental design. A method to detect and identify non-linear dependency among model parameters was suggested. The method is based on the logarithmic transformation of parameter space and the principal component analysis of the Fisher information matrix. The technique can also be used to approximate the admissible level of the observational error. The non-linear D-optimal design of observations was studied. NTIS

THE IMAGE DIGITIZING SYSTEM (IDS) Scientific Paper
Maurits Roos Jan. 1994 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275341; TEC-R-209) Avail: CASI HC A03

The conversion of mapping technology in the DOD community from analog- to digital-based technology, which started in the 1980's required precise equipment to convert aerial photographs to digital data (pixels). These are referred to as image scanners or digitizers. This paper describes the recent development of a precise image scanner by the Topographic Engineering Center (TEC) (formerly ETL). A contractor successfully developed this scanner, called the Image Digitizing System (IDS). This paper describes the general design and operation of the system, and many of its unique characteristics. The paper also describes several test results, that verify the high-geometric and high-photometric characteristics of the IDS. DTIC

REMOTE SENSING AND THE EARTH [RIMOTO SENSHINGU TO CHIKYU]
Yoshinori Ishii *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 9-40 In JAPANESE Original contains color illustrations (For primary document see N94-29217 08-43)
Avail: CASI HC A03/MF A03

Recent global problems consist of three factors which are related to one another; population, natural resources and environment. For example, increase of population enlarges energy consumption which leads to burning

of a mass of petroleum, which would result in environmental disruption and global warming. In human history, energy is closely associated with civilization; in the early stage, woods were the only energy source, then coal, petroleum, and nuclear energy is used today. Most of such earth resources produce carbon dioxide which causes global warming by the greenhouse effect. Therefore new energy sources are proposed to protect the environment, such as sunlight, agricultural wastes, hydropower, wind and geothermal energy. However, a more direct and easier method is to improve the energy efficiency. Recently, interest has been focused on remote sensing as a method to resolve these problems by observing the Earth from a macro and global viewpoint. For more practical applications, future satellites will be small systems which require low cost and short development period. We also require a new science that can integrate human and earth science and can regard the Earth as one system.

Today, several countries launched satellites for geophysical observation, which includes stationary satellites and polar satellites. By combination of these satellites, it is possible to observe the entire Earth. The low resolution and wide swath data can be used for global observation, such as meteorology, oceanic survey, forestry and disaster observation, while high resolution and narrow swath data can be used for regional observation such as land usage and survey of plant ecology and natural resources. To realize the application of remote sensing data, it is necessary to build a sufficient number of receiving stations. When enough stations are linked by relay satellites, a network to observe the whole Earth will be completed. Japan is planning to build automatic receiving stations to cover all over Japan, and collect the data at the image processing center. These data will be used for resolving global issues including desertification, natural disaster and oceanic survey, and the accumulation of the results should contribute to social activities and have the second usage for general users.

OUTLINE OF JERS-1 SYSTEM [JERS-1 SHISUTEMU NO GAIYO]

Takashi Suzuki *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 65-71 In JAPANESE (For primary document see N94-29217 08-43)

Avail: CASI HC A02/MF A03

Japanese Earth Resources Satellite-1 (JERS-1) is a geophysical observatory satellite developed for survey of natural resources as well as for observation of landscapes and disasters. It is a joint project of the National Space Development Agency and the Ministry of International Trade and Industry; the former takes charge of development of the satellite structure, system tests, launching, tracking control, and data receiving, and the latter develops mission devices. The satellite utilizes synthetic aperture radar (SAR) using L band, optical sensor (OPS) for short wave infrared observation, and a mission data recorder (MDR), all of which will show unique characteristics in global coverage, especially for lithologic mapping. The satellite structure has a system for energy supply and thermal and attitude control which is an accumulation of the latest techniques. The JERS-1 is scheduled to be launched in February 1992. The development was started in 1986 and the prototype was completed on the basis of several system development tests. At present, the flight tests are being performed using the prototype, in addition to simultaneous preparation for launch and operation in orbit.

OBSERVATORY SYSTEM OF EARTH RESOURCES SATELLITE-1 Abstract Only [CHIKYU SHIGEN EISEI 1 GO (ERS-1) KANSOKU SHISUTEMU NI TSUITE]

Mitsuru Takei *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 73 In JAPANESE (For primary document see N94-29217 08-43)

Avail: CASI HC A01/MF A03

The Japanese Earth Resources Satellite-1 (JERS-1) has been developed as a joint project of the National Space Development Agency (NASDA) and the Ministry of International Trade and Industry dominantly for survey of natural resources, as well as for observation of landscape and environmental change, oceanic survey, monitoring of disaster, and reconnaissance of coastline. The observatory system consists of Synthetic Aperture Radar (SAR), Optical Sensor (OPS), Mission Data Recorder (MDR) and Mission Data Transmitter (MDT). The SAR is an active sensor using L band which enables all-weather observation, and the data will be used for lithologic survey. The OPS includes Visible and Near Infrared Radiometer (VNIR) and Short Wave Infrared Radiometer (SWIR). The VNIR can collect three-dimensional geographical data, and SWIR will be used to identify rocks. Having completed flight tests using the prototype, the observatory system was delivered from March to September 1990 to NASDA which takes charge of development of the satellite body. The JERS-1 is scheduled to be launched in winter 1992, and to collect observatory data for two years.

APPLICATION OF JERS-1 DATA TO GEOLOGIC ANALYSES [CHISHITSU KOZO KAISEKI ENO JERS-1 DETA NO RIYO]

Yasushi Yamaguchi *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 75-95 In JAPANESE (For primary document see N94-29217 08-43)

Avail: CASI HC A03/MF A03

The Japanese Earth Resources Satellite-1 (JERS-1) is an orbiting geophysical observatory satellite unique in loading Synthetic Aperture Radar (SAR) and Optical Sensor (OPS). This report discusses predictable JERS-1 data from the viewpoint of an end-user who deals with remote sensing as a geologist. The first characteristic of SAR data is the ability of transmittance. Since SAR scans the Earth surface with microwaves which can pass through clouds and fog, observation will be possible anytime in any weather. Although JERS-1 uses L band that can penetrate deeper than X band used in previous observation, it is difficult to observe soil and rocks over plants. The second characteristic is off-nadir angle which is set at 35 deg in JERS-1; in general, large off-nadir angle lessen geographical distortion, while small angle is excellent in distinguishing surface substances. From the standpoint of a user, it is ideal to have a changeable off-nadir angle. For the same reason, a changeable SAR parameter will improve the ability to distinguish and identify the surface changes multidisciplinarily. So far, both can be realized by comparing data of the same region among satellites with different parameters or off-nadir angles. It is expected in JERS-1 that application of four bands in short wave infrared region makes it possible to distinguish rock phases in detail, and that stereo observation will also be realized by the OPS. These functions will improve lithologic data.

Advance of sensors makes it possible to obtain various kinds of remote sensing data, most of which have been applied for natural resource survey. Remote sensing includes an optical sensor and microwave sensor. Latest optical sensors used in geophysical observatory tend to have high-resolution and multi-band function, and they can collect a huge volume of data. It is planned that a sensor of short wave infrared will be applied in a satellite

observation, which will also improve natural resource survey. The remote sensing data is used for resource survey by the following three methods: (1) structural geological analysis using a small-scale image of large area; (2) structural geological analysis using a large-scale image of small area, which also makes a spectral observation possible when using multi-band sensor; and (3) collection of general information on land surface of a candidate site. The software to analyze remote sensing data has not reached a fully practical usage, however, systems to analyze the images and to identify the objective rocks are being developed. Author (NASDA)

RADAR APPLICATIONS AT THE CANADA CENTRE FOR REMOTE SENSING
V. R. Slaney *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 103-107 (For primary document see N94-29217 08-43)
Avail: CASI HC A01/MF A03

The Canada Centre for Remote Sensing (CCRS) is a Branch of the Department of Energy, Mines and Resources of the government of Canada. The CCRS was formed to support remote sensing technology in Canada by operating satellite receiving stations and facilities for processing and disseminating satellite data. These ground receiving stations are now processing LANDSAT, SPOT and AVHRR (Advanced Very High Resolution Radiometer) data routinely, and will be prepared to receive data from ERS-1, the Japan Earth Resource Satellite-1 (JERS-1) and RADARSAT. CCRS scientists are grouped into five Divisions; Applications, Methodology, User Services, Satellite Operations and Airborne Operations. The Applications Division is mainly concerned with developing and demonstrating practical ways to apply remotely sensed data to the management of Canada's natural resources. Studies are presently carried out in forestry, agriculture, hydrology, geology, oceanography, ice and, most recently, in monitoring global change. This report provides outline of investigation and operation of CCRS according to each field. Author (NASDA)

APPLICATION OF REMOTE SENSING TECHNIQUES IN PETROLEUM EXPLORATION: THE INDONESIAN EXPERIENCE
B. Situmorang *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 109-125 (For primary document see N94-29217 08-43)
Avail: CASI HC A03/MF A03

The extensive application of remote sensing techniques used in petroleum exploration for a general geological mapping and hydrocarbon exploration in Indonesia is presented. The Japanese Earth Resources Satellite-1 (JERS-1), which will be launched in early 1992, appears to have some advantages over the U.S. Landsat and French SPOT, especially for Indonesia. They are: high spatial resolution will permit more detailed mapping as in the case of SPOT; the availability of a long wavelength synthetic aperture radar (SAR) will permit penetration of cloud cover and dense vegetation; the stereoscopic capability of JERS-1 (as in SPOT) will be very useful in structural interpretation, making possible the recognition of the structural framework of basinal areas; and short wave infrared bands will enable the differentiation of clay minerals, which are very useful in studying the hydrothermal alteration zones. It appears that various advantages that have been provided by Landsat, SPOT, and radar are integrated in JERS-1. With the setting up of the Image Processing Laboratory for Oil and Gas Study at Lemigas, which is funded by the government of Japan, it shall be possible to develop image processing and analytical techniques to obtain optimum geological information for hydrocarbon exploration.

EOS PROJECT AND ASTER (ITIR)
Hiroji Tsu *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 127-153 (For primary document see N94-29217 08-43)
Avail: CASI HC A03/MF A03

The Earth Observing System (EOS) project is a plan to understand global changes using satellite observatory data, mainly under the direction of NASA. The scientific mission of EOS aims at collecting data to enlarge knowledge of relevant academic fields and multidisciplinary intervention, and to recognize how the earth system is changing. It has been decided that nine sensors are planned for EOS-A, one of which is the advanced spaceborne thermal emission and reflection radiometer (ASTER) (intermediate thermal infrared radiometer (ITIR)) proposed by the Ministry of International Trade and Industry, Japan. ASTER is a unified imaging system that can detect visible through thermal infrared spectra, and can make images with both high spatial and spectral resolutions. This scientific mission will be performed with close collaboration between Japanese and U.S. ASTER science teams. The ASTER project is managed by the Ministry of International Trade and Industry, under which Japan Resources Observation System Organization (JARO) takes charge in development of sensors, and Earth Resource Satellite Data Analysis Center (ERSDAC) is responsible for processing and analyses of the data and user services.

EARTH-OBSERVATION PLAN IN EUROPE
G. Triebnig *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 155-162 (For primary document see N94-29217 08-43)
Avail: CASI HC A02/MF A03

It has become increasingly obvious that humans are faced with a number of potentially major environmental problems (e. g. climatic change due to the greenhouse effect, ozone depletion). Observation of the Earth from space is one of the keys to a better understanding of the Earth as a system and is vital to achieving a comprehensive assessment of the influence of man's activities on the environment. Observation of the Earth and its environment has been part of the European Space Agency's (ESA) programs since the advent of the METEOSAT program in the early 1970's. The all-weather satellite ERS-1 will provide a new perspective in the early 1990's for better understanding and monitoring the Earth and its environment. Future plans of the Agency include the following: ERS-2, a follow-on mission to ERS-1; a solid Earth gravity mission; a second generation METEOSAT with improved capabilities; and a series of polar-orbit missions to provide a wide range of observations of the Earth which are particularly important for monitoring and understanding the environment. ROCK IDENTIFICATION USING THERMAL INFRARED DATA
Anne B. Kahle *In* Earth Resources Satellite Data Analysis Center, Proceedings of the 3rd International Symposium: JERS-1 and Remote Sensing in the Future 29 Mar. 1991 p 163-174 Original contains color illustrations (For primary document see N94-29217 08-43)
Avail: CASI HC A03/MF A03

The Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER) instrument will be the first spaceborne multispectral thermal infrared instrument with spatial and spectral resolution adequate for geologic applications. From thermal data one can derive both surface temperature and surface spectral emissivity. The primary application of the emissivity is for surface lithologic mapping. The temperature data can be used for studies of thermal inertia of surface materials and for studies of thermal processes related to volcanism and hydrology. This report describes the theoretical background and examples of the use of multispectral thermal data. From theoretical and experimental framework, the ASTER instrument will allow mapping and identification of most terrestrial rocks, such as silicates, iron oxides, carbonates, and clay minerals. The importance of multispectral thermal data was demonstrated by NASA's Airborne Thermal Infrared Multispectral Scanner (TIMS) which clearly imaged rocks and temperature, especially for mineral survey. Avail: CASI HC A02/MF A03

Although global environmental change is closely related with agriculture, the influence of environmental change on agriculture and environmental disruption by agricultural production have not been analyzed quantitatively. The amount and change of factors in a global ecological system should be determined in a global scale for grasping agroecological problems. This is difficult to do by conventional methods, but remote sensing is expected to be able to collect these data accurately and promptly. In industrialized countries, environmental change is a concern due to global warming and depletion of the ozone layer by increases in the use of chemical products and by the burning of petroleum products. Water pollution by toxic substances and acid rain have been spreading. On the other hand, in developing countries, rapid increases in population promote desertification and degeneration of soil and tropical rain forests. There are also problems with pollution that are similar to those of the industrialized countries. In order to cope with these problems, a sensor with high spatial and spectral resolution is necessary. For these reasons, it is essential to develop a technique to process remote sensing data to obtain detailed and practical information for agroecology. Author (NASDA)

The expectation of applying remote sensing in monitoring disasters has increased recently. To prevent disasters, it is necessary to obtain the most recent information on natural and social changes; rapid analysis, advice, and cooperation by specialists are important. Remote sensing is excellent for monitoring disasters for a long-term periodically, and sudden occurrences will be able to be monitored when an all-weather and all-day sensor, Synthetic Aperture Radar (SAR), is applied. Improvement of communication and transmission systems is also necessary to cope with disasters quickly and effectively. Today, the remote sensing is applied in prevention of disasters in various fields (such as floods, landslides, volcano eruptions, and earthquakes) and has provided useful information worldwide. Future disasters are considered to be closely associated with global environmental changes, so that the emphasis on remote sensing and international cooperation should be increased to resolve these problems.

Avail: CASI HC A03/MF A03

This panel discussion focused on the future of remote sensing. The participants were specialists of various scientific fields associated with remote sensing. Possible applications to geographical study and natural resources surveys, predictable data collected by Synthetic Aperture Radar (SAR) and Optical Sensors (OPS) to be loaded in Japanese Earth Resources Satellite-1 (JERS-1), expectations of the international society of remote sensing, practical and low-cost applications of remote sensing data, international evaluation of JERS-1 especially with respect to the SAR sensor, and the desired function of a future sensor are main topics. Comparison of development of remote sensing among Europe, the USA and Japan, and what should be done in the next decade was also discussed. Emphasis is made on the use of remote sensing data not only for Japan but on a global scale. Author (NASDA)

ON THE TEMPERATURE DISTRIBUTION NEAR A COLD SURFACE
Yin-Chao Yen Oct. 1993 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275162; CRREL-93-19) Avail: CASI HC A03

Temperature profiles were taken during the 1991-92 season at an experimental site on CRREL's grounds; however, they were rather limited because of the unusual lack of snowfall and the location of the site, which was small and had elevated sides (especially in the direction of the prevailing wind). Nevertheless, some unusual features have been observed for the first time. The profiles show the existence of a double-reversal in temperature structure close to the snow surface when the snow temperature is much lower than its melting point, in contrast to a persistent raised maximum temperature over a melting snowpack. This indicates that the micro-heat transport process is complicated by the presence of a non-isothermal lower boundary. Over frozen or partially frozen ground without snow, and with air temperature either above or below the melting point of ice, a thin, nearly isothermal air layer on the order of 2 to 3 cm in thickness at varying heights was observed for the first time. With very few exceptions, in general, the temperature decreases as height increases, but the extent is less pronounced over a snow cover (where conditions are nearly isothermal) than over cold ground. On the basis of limited measurements, the overall temperature gradient over the bare ground is about twice that over snow-covered ground. DTIC

AN EARTH OBSERVATION TELESCOPE REFOCUSING MECHANISM
M. Lavadoux (Societe d'Applications Generales d'Electricite et de Mecanique, Cergy-Pontoise, France.) and J. F. Patin 1993 6 p
(Rept-932-440-103; ETN-94-95474) Avail: CASI HC A02/MF A01

The development, requirements, and testing of the refocusing mechanism of a space telescope are reported. The refocusing mechanism that was developed holds the focus lens in the nominal flight position throughout the launch phase, and acquires and maintains the focus lens position during observation to compensate for dimensional variations in the telescope in orbit. The refocusing mechanism developed for this observation satellite is particularly interesting because of its high precision characteristics. Its two innovating originalities are essentially its translatory motion guidance device using two parallel deformable leaves and its linear actuator, which is highly efficient for its characteristics of precision, life time, and environmental ability. To date, this mechanism has been validated by several elementary tests that have enabled qualification of the technologies and components: stepper motor, coupling belows, linear actuator, ball bearings, guidance device, locking device, and transmission arm. FRONTS AT THE CONFLUENCES OF SPRING-FED STREAMS WITH JOEKULSA A FJOELLUM: POSSIBLY THERMAL BARS?
Anthony Kay Oct. 1993 12 p Original contains color illustrations
(MATHS-Rept-A-198; ETN-94-95513) Avail: CASI HC A03/MF A01

Remarkably sharp fronts observed where spring water streams flow into the glacial river Jokulsa a Fjollum, which flows northwards from the ice cap Vatnajoekuli to the north coast of Iceland. Reasons for speculating that these fronts are thermal bars resulting from the temperatures of the river water and the spring water being on opposite sides of the temperature of maximum density are given. It is suggested that measurements of temperature and flow profiles across the fronts are to be made in order to determine whether this is indeed the correct explanation. Ideas for future research are given. ESA

AUTOMATING GEOGRAPHICALLY REFERENCED DIGITAL MOSAICS FROM AERIAL VIDEOGRAPHY WITH AREA-BASED FEATURE MATCHING Ph.D Thesis
Douglas Frank Wunneburger 1992 121 p
Avail: Univ. Microfilms Order No. DA9315164

Resource managers are frequently in need of high resolution imagery within short turn-around periods. Videography provides a source for such data. Current videographic capabilities are limited by the narrow field of view of the sensor and the lack of geographic reference. However through automated processing, digital mosaics overcome videography's narrow field of view while maintaining high resolution and large scale. Aerial videography has several advantages over conventional photographic and satellite remote sensing data. Photographic processing costs and time are virtually eliminated, and unlike pushbroom type scanners, stereo coverage is achieved in each single flight line. Using dynamic GPS (global positioning system) locators with videography, it is possible to generate geo-referenced images. Upon capturing these images in digital form, machine vision area matching procedures provide the capability to generate automated digital mosaics with multiple geo-referenced anchor points. The project integrates aerial videography, geographic referencing systems, and area based feature matching to produce a system able to generate referenced mosaics of contiguous videographic images. INTER-COMPARISON OF WILDFIRE AND HIGH-RESOLUTION INTERFEROMETER SOUNDER (HIS) DATA FROM STORM-FEST: AN INVESTIGATION OF WILDFIRE SPECTRAL CHANNEL DISCREPANCIES
G. J. Jedlovec and G. S. Carlson Mar. 1994 31 p
(NASA-TM-108439; NAS 1.15:108439) Avail: CASI HC A03/MF A01

This simultaneous collection of HIS spectral measurements aboard the ER-2 during STORM-FEST provided a means to explore calibration problems in the infrared bands of the Wildfire instrument. Large discrepancies in brightness temperatures were noted in Wildfire bands designed to sample the 'wings' of the strong ozone absorption band centered at 9.6 microns, where the atmospheric transmittance changes rapidly with wavelength. Examination of interchannel relationships in Wildfire data and subsequent comparison to Wildfire data synthesized from the HIS measurements suggests that a wavelength shift in the channel spectral response from those determined in the laboratory may have occurred. Based on comparisons from several flights, this spectral shift has been empirically determined to be about 0.15 micron. It is speculated that this problem resulted from a slight misalignment of the spectrometer grating or other optical elements, or was a result of extreme range in temperatures experienced by the instrument throughout the course of an ER-2 flight. A consequence of this temperature fluctuation may be a change in a position of the grating in the optical path and could result in the variations in channel spectral response during flight. These findings for Wildfire may have significant bearing on future use of the MAS because of the similarities to the original Wildfire configuration. Author (revised)

A SIMULATION STUDY OF HIGH DEGREE AND ORDER GEOPOTENTIAL DETERMINATION USING SATELLITE GRAVITY GRADIOMETRY Ph.D. Thesis
Srinivas Viswanath Bettadpur 1993 172 p
Avail: Univ. Microfilms Order No. DA9323340

For several applications in oceanography and geophysics, there is an evident need for the determination of high resolution global geopotential fields to a great accuracy. The problem of estimation of high degree and order spherical harmonic expansions of the geopotential from satellite measurements of gravity gradients has been studied in the framework of a numerical simulation study of the Aristoteles gravity gradiometer mission. Computational issues in high speed spherical harmonic synthesis and large least squares estimation are discussed in detail. The focus has been on the development of highly vectorized and parallelized algorithms for these computations. The resulting estimation software is seen to sustain 90 percent of peak performance on a CRAY Y-MP, facilitating simulations for large gravity fields with reasonable computer expenses. Appropriate noise models for the gravity gradients measured in the ESA Aristoteles mission scenario have been developed. Detailed analysis is presented of the instrument colored and white noise. The spectral and spatial distribution of the drag errors in the presence of density and wind perturbations in the atmosphere has been studied. The resulting error gradient models include effects due to the instrument noise, drag residuals and angular velocity errors. From the simulated measurements of the radial gravity gradients, the coefficients of a degree and order 100 model of the geopotential have been estimated. A comparison of the estimates made using a dense and a sparse linear system method from the literature is also given. The results indicate that the largest errors in the geopotential are caused by drag, with the instrument, attitude and orbit errors being of secondary importance. The sparse system method is seen to be inadequate in comparison to the dense linear system simulations. It is concluded that for gradiometer data analysis, dense linear system methods are a viable option, even though computationally expensive. The results from these simulations indicate that the long wavelength geopotential cannot be determined with any significant accuracy in the assumed Aristoteles mission and error scenario, requiring possible augmentation with other data types. At higher frequencies, however, the geoid errors appear acceptably low, indicating that such a mission might provide significant improvements in the knowledge of the high frequency geopotential. Dissert. Abstr.

THE USES AND LIMITATIONS OF FRACTAL GEOMETRY IN DIGITAL TERRAIN MODELLING Ph.D. Thesis
Zong-Guo Xia 1993 263 p
Avail: Univ. Microfilms Order No. DA9315515

In this study, fractal concepts and techniques are tested using nearly 200 DEM's (digital elevation models) produced by the USGS. The specific objectives include (1) an examination of statistical self-similarity of topographic data; (2) an evaluation of three most commonly used methods for estimating the fractal dimension of topographic surfaces; (3) a preliminary test of using fractal parameters to characterize various landforms and to delineate landform regions; and (4) an examination of the relationships between fractal parameters and geomorphic variables affecting landform characteristics. The analysis of the computational results has led to the following conclusions: (1) the fractal model fits certain types of terrain surface better than others, and topography is only self-similar within quite limited scale ranges and in certain direction(s); (2) the fractal dimension of landforms varies within a wide range, the fractal dimension used to produce realistic-looking synthetic terrain ($D = 2.2$) only represents some special type of terrain surface, and a D value of 2.5 obtained by some early researchers is merely a result of artificial agglomeration of diversified terrain surfaces; (3) most DEM's from the mountain regions can be easily separated from those of plains or plateaus, and the fractal parameters of adjacent physiographic provinces are significantly different so that fractal segmentation of landform regions appears possible; (4) fractal parameters reflect well the effects of lithology, geological structure, and the stage of landform evolution on landform characteristics, but no clear relationship between fractal parameters and climate was identified possibly due to the relatively coarse resolution of the data; and (5) the variogram method is the most suitable method for estimating the fractal dimension of topographic profiles or surfaces, the box-counting method also produces reasonable results when careful consideration is given to the selection of the maximum cell

size, the contour interval and the minimum r-squared value, and the walking dividers method can not be easily applied to self-affine fractals such as topographic profiles. Dissert. Abstr.

EXTRAPOLATION OF POINT DATA FOR RESOURCE MAPPING Ph.D. Thesis
David William Long 1992 103 p
Avail: Univ. Microfilms Order No. DA9315359

Since the early seventies, the usefulness of satellite imagery for producing vegetation maps has been well known. Even small scale imagery such as advanced very high resolution radiometer (AVHRR) has been applied to continental vegetation mapping. Much has been written about how remote sensing can provide this kind of data for a GIS (Geographic Information System), however, little attention has been placed on the role of GIS for supplying data to automate the image classification process. Large data bases such as the USDA SCS National Resources Inventory (NRI) now being constructed have a potential for filling this role. The NRI has a potential for contributing to the improvement of vegetation mapping in at least three ways: Automated classification of imagery using NRI sample points to create training sets, classification verification through use of NRI sample points as field verification points, and automated map generation directly from the NRI data base through use of Thiessen polygons. Classification accuracy of a TM scene classified using NRI data to produce training sets was fair (43.6 percent overall classification accuracy) considering the process was completely automated with no human judgment involved. Adding ancillary data and temporal image information should improve this figure. Classification accuracy was tested for training sets of various sized polygons constructed around the NRI points. It was found that the smallest polygon (3 x 3 box) around each point resulted in a training set that produced the most accurate classification. Land use/land cover maps can be easily generated from the NRI data base using the Thiessen polygon process. They provide a good overview of the conditions for a large area such as a state, however, for a county sized map, there are too few NRI data points to allow a reasonable depiction of the true conditions. Thiessen polygon maps do not depict accurate boundaries due to the process used for polygon generation, however, with the large number of sample points in the NRI, they provide a quick approximation of the conditions and have a potential for displaying land use/land cover change as the NRI is updated every five years. Dissert. Abstr.

SATELLITE ESTIMATION OF THE GLOBAL DISTRIBUTION AND INTERANNUAL VARIABILITY OF PHOTOSYNTHETICALLY ACTIVE RADIATION Ph.D. Thesis
Dennis Gene Dye 1992 196 p
Avail: Univ. Microfilms Order No. DA9315635

Photosynthetically active radiation (PAR) (400-700 nm) is a fundamental resource for global primary production, but existing data sources have been insufficient to provide a reliable, quantitative account of global PAR distribution and variability. The objectives of this research were as follows: (1) evaluate the accuracy of a new satellite remote sensing method for estimating and monitoring incident PAR on a global basis; and (2) evaluate the magnitude, distribution, and interannual variability of global incident PAR to determine its potential significance as a factor contributing to variability in global patterns of vegetation-absorbed PAR (APAR) and primary production. The method employs ultraviolet (370 nm) reflectance data from the Nimbus-7 Total Ozone Mapping Spectrometer (TOMS) with a maximum spatial resolution of 1 deg x 1.25 deg. The study covers the 11-year period between Jan. 1979 and Dec. 1989 and latitudes between 66 deg N and 66 deg S. Validation of monthly PAR estimates at sample points produced coefficients of determination (r2) between .863 and .996 and RMS differences between 2.8 and 16.1 percent. Possible sources of error in both the satellite estimates and reference data are identified. The global analysis identified distinct regions of substantial inter annual variability in incident PAR. Coefficients of variation (CV) as high as 18-24 percent for the growing season months and 4-7 percent for annual PAR were observed in Europe, China, Southeast Brazil, and Northern Australia, among other regions. CV's as high as 20 percent for monthly PAR and 8 percent for annual PAR in the western tropical Pacific Ocean region may be associated with El Nino-Southern Oscillation (ENSO) conditions. Deviations in global average PAR observed in 1982 suggest possible global-scale effects of the El Chichon volcanic eruption and/or ENSO. The results from the study confirmed that many regions of the globe are subject to substantial interannual variations in monthly and annual amounts of PAR received. Based on understanding from current physical models and evidence from recent field investigations, this variability represents a significant, potential source of variability in vegetation-absorbed PAR (APAR) and primary production. Dissert. Abstr.

USE OF SATELLITE DATA TO IMPROVE PARAMETERIZATION OF SPATIAL AND TEMPORAL VARIATIONS OF GASEOUS DRY DEPOSITION IN REGIONAL-SCALE MODELS
Wei-Gang Gao and M. L. Wesely 1994 8 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994
(Contract W-31-109-eng-38)
(DE94-005110; ANL/ER/CP-80787; CONF-940115-20) Avail: CASI HC A02/MF A01

The removal of gaseous substances from the atmosphere by dry deposition represents an important sink in the atmospheric budget for many trace gases. Hence, the surface removal rate needs to be described quantitatively in modeling atmospheric transport and chemistry with regional- and global-scale models. Because the uptake capability of a terrestrial surface is strongly influenced by the type and condition of its vegetation, the seasonal and spatial changes in vegetation should be described in considerable detail in large-scale models. The objective of the present study is to develop a model that links remote sensing data from satellites with the RADM dry deposition module to provide a parameterization of dry deposition over large scales with improved temporal and spatial coverage. This paper briefly discusses the modeling methods and initial results obtained by applying the improved dry deposition module to a tallgrass prairie, for which measurements of O3 dry deposition and simultaneously obtained satellite remote sensing data are available. APPLICATION OF REMOTE SENSING TECHNIQUES FOR THE SEISMO-TECTONIC STUDY OF NAHANNI EARTHQUAKE AREA M.S. Thesis
Bo Li Aug. 1993 247 p
(ISBN-0-315-85942-3; CTN-94-61173) Copyright Avail: Micromedia Ltd., Technical Information Centre, 240 Catherine Street, Suite 305, Ottawa, Ontario, K2P 2G8, Canada HC/MF

Three major earthquakes occurred in 1985 and 1988 near the south branch of the North Nahanni River, Northwest Territories. A detailed investigation is presented of the local earthquake tectonic activities, using remote sensing images, earthquake data, and other relevant information. An integrated data processing approach is applied to the analysis, including the integration of different remote sensing data sets. Multispectral satellite images from the Landsat MSS and SPOT, as well as airborne C-band synthetic aperture radar images, are geometrically corrected and enhanced for linear feature interpretation. The Hough transform is implemented and tested for automatic mapping of linear features from remote sensing images. Digital seismograms are utilized to obtain focal parameters of the main shocks and aftershocks of the Nahanni earthquakes. The mapped linear features and focal parameters are then correlated to study the structural geological mechanisms and faulting processes associated with the three main events. Both remote sensing images and earthquake data indicate that the west-dipping thrust faulting is active in the earthquake processes, particularly where it meets the new east-west striking faults. Several linear patterns mapped provided additional information about the tectonic setting and local geological structures related to the earthquakes. Author (CISTI)

Standard image analysis methods developed for satellite based remotely sensed images do not appear to be appropriate for high resolution digital

images from airborne systems. A new approach to the analysis of the latter type of image is presented. This approach, combined with a new approach to the cartographic representation of the image analysis results, is seen as potentially more appropriate for the needs of operational forestry and other uses. A study was conducted of a region within an Ontario forest. Mature trees of three conifer species were examined in detail, and a simple technique using local image maxima was employed to isolate individual trees. A new method of computing tree density using the Voronoi diagram and individual tree positions was investigated. Continuous density surfaces were computed for each species distribution using an interpolation method based on the Voronoi diagram. The results were then validated from inventories based on individual tree positions. The resulting stem estimates agreed relatively well with the ground information, and appeared to reproduce the local variations in stem density distribution of each species. Author (CISTI)

AIR-DEPLOYABLE GEOPHYSICS PACKAGE
S. L. Hunter and P. E. Harben Nov. 1993 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-48)
(DE94-005651; UCRL-ID-115370) Avail: CASI HC A03

We are using Lawrence Livermore National Laboratory's (LLNL's) diverse expertise to develop a geophysical monitoring system that can survive being dropped into place by a helicopter or airplane. Such an air-deployable system could significantly decrease the time and effort needed to set up such instruments in remote locations following a major earthquake or volcanic eruption. Most currently available geophysical monitoring and survey systems, such as seismic monitoring stations, use sensitive, fragile instrumentation that requires personnel trained and experienced in data acquisition and field setup. Rapid deployment of such equipment can be difficult or impossible. Recent developments in low-power electronics, new materials, and sensors that are resistant to severe impacts have made it possible to develop low-cost geophysical monitoring packages for rapid deployment missions. Our strategy was to focus on low-cost battery-powered systems that would have a relatively long (several months) operational lifetime. We concentrated on the conceptual design and engineering of a single-component seismic system that could survive an air-deployment into an earth material, such as alluvium. Actual implementation of such a system is a goal of future work on this concept. For this project, we drew on LLNL's Earth Sciences Department, Radio Shop, Plastics Shop, and Weapons Program. The military has had several programs to develop air-deployed and cannon-deployed seismometers. Recently, a sonobuoy manufacturer has offered an air-deployable geophone designed to make relatively soft landings. DOE

A MONOTONICITY CONJECTURE FOR REAL CUBIC MAPS
S. P. Dawson, R. Galeeva, J. Milnor, and C. Tresser 1993 18 p Presented at the NATO/ASI Meeting on Real and Complex Dynamical Systems, Hillerod, NJ, Jun. 1993
(Contract W-7405-eng-36)
(DE94-003969; LA-UR-93-3844; CONF-9306286-1) Avail: CASI HC A03/MF A01

This will be an outline of work in progress. We study the conjecture that the topological entropy of a real cubic map depends 'monotonely' on its parameters, in the sense that each locus of constant entropy in parameter space is a connected set. This material will be presented in more detail in a later paper. DOE

FAME: A FOREST ASSESSMENT AND MONITORING ENVIRONMENT SCENARIO
Wim J. Looyen, Frank O. Zeppenfeldt, Jan Cees Venema, Gert vandenBurg, Dirk H. Hoekman, Joost J. vanderSanden, Paul G. Reichert, and Eduard Westinga 26 Feb. 1993 17 p Presented at the International Symposium on Operationalization of Remote Sensing, Enschede, Netherlands, 19-23 Apr. 1993 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-B179106; NLR-TP-93047-U; ETN-94-95967) Avail: Issuing Activity (European Space Agency (ESA))

A feasibility study on a global operational forest cover monitoring network using satellite remote sensing data within the framework of the Tropical Forestry Action Plan is addressed. The study indicates that the use of remote sensing data for global forest cover monitoring is of great importance. To enable this, provisions are required to allow operational preprocessing of remote sensing data to well defined and standardized products. A scenario for the development of a Forest Assessment and Monitoring Environment (FAME) is presented. Firstly, Pilot FAME (PFAME) is developed, aiming at providing a suitable infrastructure for forest management using satellite remote sensing data to compile information on global forests. Secondly, PFAME, is upgraded to improve its functionality and to introduce forest management systems. Thirdly, PFAME is extended by introducing remote sensing data from other newly launched sensors. By introducing this three step approach, uniform and validated remote sensing end products will become available for use in sustainable forest management providing information on the state, extent and distribution of tropical forests. STATISTICAL ANALYSIS OF A SATELLITE IMAGERY TIME SERIES: IMPLICATIONS FOR THE STUDY OF COASTAL AND ESTUARINE CIRCULATION Ph.D. Thesis
Anna Maria Matteoda 1992 213 p
Avail: Univ. Microfilms Order No. DA9319093

Empirical Orthogonal Functions analysis of a thirteen month AVHRR imagery time series was performed to assess the temporal and spatial variability of turbidity patterns in Delaware Bay and the coastal area to the south. The statistical results were interpreted in light of existing knowledge of the coastal and estuarine circulation in the study area, and compared to data sets of wind and river discharge for the concurrent period of time. Several analyses, including eigenvector rotation for the EOF modes and cluster analysis, were run on different subsets of the imagery data, normalized to tidal cycle or to wind strength as well as to location within and outside the estuary. The results produced spatial patterns of variability and plots of temporal modulation of such variability over subtidal time scales; tidal cycle normalization allowed a separate examination of the variability due to tidal forcing, the dominant circulation driving force, which was inadequately sampled in the original series. The estuarine turbidity maximum variability was captured by the dominant EOF modes and corresponded to variability in the river discharge records. Analysis of the turbidity signal along the coastal zone to the south of Delaware Bay revealed a spatial pattern that is entirely consistent with the presence of a buoyant coastal current flowing out of the Delaware Estuary and hugging the coast in a southward flow, as reported recently by Garvine and Munchow. Tidal variability analysis produced ambiguous results which suggest that further study is needed in this area. The main source of error was the occasional presence of localized clouds, but it did not affect the dominant first EOF mode, because of the random nature of such error. The techniques developed for this study can be useful as a data reduction tool in the management of the large volumes of operational satellite-derived data, since the first few EOF modes summarize the variability of the data set. Dissert. Abstr.

MULTITEMPORAL ANALYSIS OF A BRAIDING RIVER: THE ADVANCED STUDY OF 1992
H. H. S. Noorbergen 15 May 1993 20 p Presented at the International Symposium on Operationalization of Remote Sensing, Enschede, Netherlands, 19-93 Apr. 1993
(NLR-TP-93100-U; ETN-94-95971) Avail: CASI HC A03/MF A01

A project which used satellite imagery for the monitoring and forecasting of the erosion of the Jamuna river banks in Bangladesh is presented. For the remote sensing analysis fifteen satellite images collected between 1973 and 1992 were processed. These images were obtained by the LANDSAT multispectral scanner, LANDSAT Thematic Mapper, and the Marine Observation Satellite (MOS-MESSR). An important criterion was to select only images from seasons with comparable low water levels in the main channels. From each year a user defined classification was made into the four categories water, sand, vegetation and bare soil. By combining the classification results of the separate years several products can be made, such as difference images between any two years, successive river courses and number of water occurrences. CHEMICAL COMPOSITION OF INSOLUBLE PARTICLES IN SUPERIMPOSED ICE ON STOROEYA, SVALBARD (SWEDEN)
Margareta E. Hansson, Hans-Christen Hansson, Stig Jonsson, and Jost Heintzenberg Sep. 1993 22 p Sponsored by Swedish Natural Science Research Council
(ISSN 0280-445X)
(CM-82; ETN-94-95851) Avail: CASI HC A03/MF A01

The chemical composition of the insoluble impurities in a seven meter long ice core of superimposed ice from the Storoeya ice cap is examined. The concentrations of fourteen elements were determined by PIXE (Particle Induced X-ray Emission) and soot photometer analyses. Si is the mass dominating element, making up 49% of the mass of determined elements, followed by elemental carbon forming 26%. Fe, K, Ca and Ti, in descending order, account for 24% while Mn, Zn, Ga, As, Rb, Sr, Zr and Pb together constitute less than 1% of the mass. Size separation by filtration, multivariate statistical analyses and calculation of enrichment factors are used to reveal the origin of the impurities. A crustal source, most likely local, is found to dominate. A second comparatively weak source, possibly anthropogenic, is suggested to contribute to 15 to 100% of the concentrations of elemental carbon, Zn, As and Pb. ESA

NEW PERSPECTIVES FOR HIGH ACCURACY SLR WITH SECOND GENERATION GEODESIC SATELLITES
Glenn Lund 1993 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Rept-932-440-105; ETN-94-95953) Avail: CASI HC A02

It was shown from link budget analyses that, when coupled with an appropriate satellite configuration, realistic single retroreflector dimensions could enable millimetric absolute accuracies to be achieved with the 2-color SLR (Satellite Laser Ranger), through the removal of center of mass uncertainties in the range determination. The engineering of retroreflector velocity aberration corrections is an important factor in the design of a geodesic satellite and in the link budget performance to be expected from the complete ranging system. Two approaches to the design of second generation geodesic satellites were suggested. Although these might imply the use of nonspherical orbiting bodies, with consequently higher atmospheric drag and solar radiation pressure imbalances than for existing satellites, they could nevertheless enable excellent geometric mode (short arc) range determinations to be achieved, and they could be expected to provide very good long arc performance for high altitude orbits. This year's theme, 'Fuel Cells: Realizing the Potential,' focuses on progress being made toward commercial manufacture and use of fuel cell products. Fuel cell power plants are competing for market share in some applications and demonstrations of market entry power plants are proceeding for additional applications. Development activity on fuel cells for transportation is also increasing; fuel cell products have potential in energy and transportation industries, with very favorable environmental impacts. This Seminar has the purpose of fostering communication by providing a forum for the international community interested in development, application, and business opportunities related fuel cells. Over 190 technical papers are included, the majority being processed for the data base. DOE

This report describes the results of the literature search, interviews, and site visits conducted during the first six months of this subcontract. This survey was conducted to establish a baseline of information about thermal and photothermal degradation of EVA and case history surveys on discoloration (yellowing/browning) of EVA-based encapsulants in fielded flat-plate PV modules. The literature search revealed that EVA will undergo thermolysis of the acetate groups at temperatures of 130 C to 150 C and above leading to formation of double bonds in the backbone of the copolymer. The survey of case histories of EVA-based encapsulant discoloration in fielded modules in the United States revealed that the problem is limited to those areas of the west and southwest that have comparatively high solar insolation and ambient temperature. It is clear that the discoloration problem is not limited to the modules of any one manufacturer. Discoloration in the EVA encapsulant was experienced in fielded modules from all major U.S. module producers. DOE

SILICON-FILM (TM) PHOTOVOLTAIC MANUFACTURING TECHNOLOGY
W. R. Bottenberg Jan. 1994 34 p Prepared for Midwest Research Inst., Golden, CO
(Contract DE-AC02-83CH-10093)
(DE94-000258; NREL/TP-411-6110) Avail: CASI HC A03/MF A01

AstroPower is in the second phase of a 3-year, phased effort to upgrade its facility to produce 1.22-sq m Silicon-Film(trademark) PV modules with an output of 170 W(sub p). Productivity improvements of the Silicon-Film(trademark) machine were accomplished during the second phase. Improvements were made in solar cell performance while decreasing materials consumption, integrating and mechanizing the fabrication process for solar cells, and scaling-up solar cell and module equipment for fabricating larger cells. AstroPower is continuing work on separating out effects due to impurities and effects due to defects. Analytical tools were developed for measuring area-based response based on EBIC and LBIC methods. The Kauffman source for hydrogen ion implantation was used to map out the process space for Silicon-Film(trademark) solar cell improvement. Progress was made on improving short-circuit current. Areas of focus include

developing tools to quickly assess material quality; developing a hydrogen implantation process; increasing material quality on large-area, high-throughput wafers; and studying potential processes for improving solar cell power output during cell fabrication. A method to improve current collection in a solar cell after contact formation is under development. DOE

FISCAL 1991 GEOTHERMAL DEVELOPMENT PROMOTION ENERGY
Feb. 1993 119 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-732332; ETDE/JP-mf-94732332) Avail: CASI HC A06

The paper surveys the spouting of geothermal fluids in test boring wells, the well logging, and the status of geothermal fluids, as a part of the geothermal development promotion survey in the Mizuwake-Toge south area. In the spouting test of N3-MW-6 well, the 53rd swabbing led successfully to spouting. The spouting amounted to 3.6 tons/h in steam and geothermal water, but stopped spontaneously in 100 minutes. Results of the logging are hardly different between before and after the spouting indicating a maximum temperature of 200 C, barometric pressure of 75, and water levels of a 250-300m section. The geothermal water is a neutral Cl deep-area type. N2-MW-2 well spouted immediately after the 10th swabbing, indicating steam of 3 tons/h at the stable time, geothermal water of 7.3 tons/h, pH9, Cl of 1500ppm, and the total spouting time of 4029 minutes. The place where the geothermal fluid flows in is 635m deep, and when the well head pressure was 1.7-3.9 barometric pressure, the spouted fluid temperature was 199-198 C. The geothermal water is a Cl-HCO3 type. In both wells geothermal water is ground water originated from meteoric water which reacted with peripheral rocks by volcanic heating and was formed in the deep area. DOE

FISCAL 1990 GEOTHERMAL DEVELOPMENT PROMOTION SURVEY
Mar. 1992 366 p
(DE94-732333; ETDE/JP-mf-94732333) Avail: CASI HC A16/MF A03

The development of a geothermal reservoir evaluation method is mentioned for the purpose of reducing the risk of the geothermal development and drawing up an appropriate power generation plan. As for simulators, a geothermal reservoir simulator (SING-I,II) and a geothermal well two-phase simulator (WENG) are developed. For SING-II, an evaluation is made of fracture effects in the pressure interference test, production predicting simulation using fracture models, development of a multicomponent gas-liquid two-phase simulator and a tracer simulation function. As to WENG, verification on fluids containing CO2 and survey on fluids containing NaCl are made. In the Mori area which is a model field, continued observation on reservoir pressure is conducted as well as temperature/pressure logging and chemical analysis of spouted fluids. By three-dimensional grid models of reservoirs, reappearance of natural conditions of temperature/pressure distribution and discharge into the ground surface can roughly be made, and history matching is tried to be made. Newly also in Oguni area, reappearance of natural conditions is simulated using SING-I. DOE

REPORT OF FEASIBILITY STUDY ON INTERNATIONAL-COOPERATION IN HIGH EFFICIENT ENERGY CONVERSION TECHNOLOGY
Mar. 1993 250 p
(DE94-732340; NEDO-P-9255) Avail: CASI HC A11/MF A03

With regard to accelerated introduction of high efficient energy conversion technology to developing countries, the paper investigates the countries' thoughts of the introduction of the technology and the status of the introduction bases. The countries for survey are the Philippines, Indonesia, Malaysia and Thailand. The Philippine government expects to develop cogeneration as well as large power sources and to widen effective use of natural energy. In Indonesia, they largely expect effective use of biomass energy using Stirling engines by international cooperation and the promoted local electrification using standalone distributed fuel cells. In Malaysia, they have great expectations of the introduction of air conditioning facilities using Stirling engines and the use of standalone distributed fuel cells for promotion of local electrification. Thailand hopes for the use of Stirling engines to air conditioning systems, and the development of solar Stirling generators with solar energy as a heat source and electric vehicles. DOE

QUALITY AND EFFICIENCY OF SOLAR COLLECTORS IN SWEDEN [SOLFANGARES KVALITET OCH BESTAENDIGHET I SVERIGE. DEL 2. KONVEKTIONSHINDER AV FEP-FILM-SKADEUTREDNING]
H. Wennerholm 1993 99 p In SWAHILI
(PB94-137486; SP-RAPP-1993:17) Avail: Issuing Activity (National Technical Information Service (NTIS))

Transparent or translucent insulation materials (TIM's) represent a new class of materials with a high potential for increasing the efficiency of solar thermal conversion systems. A large number of materials have been subjected to theoretical and experimental investigation. If materials that suppress heat losses are transparent to solar radiation, vacuum, certain gases, convection barriers, etc., then they can be regarded as TIM's. Exploratory field and laboratory studies of degraded FEP-film convection barriers in flat plate thermal solar collectors are described. The study related to collectors that had been operating in Sweden for periods of one year to ten years. Both physical, functional (thermal) and chemical aspects of degradation were considered. The report identifies the mistakes made so that they need not be repeated by the solar collector manufacturers in the future. NTIS

PERFORMANCE OF THE SOUTHERN CALIFORNIA EDISON COMPANY STIRLING DISH
C. W. Lopez (Southern California Edison Co., Rosemead.) and K. W. Stone (Mako Enterprises, Huntington, CA.) Oct. 1993 211 p
(Contract DE-AC04-94AL-85000)
(DE94-004676; SAND-93-7098) Avail: CASI HC A10/MF A03

McDonnell Douglas Astronautics Company (MDAC) and United Stirling AB of Sweden (USAB) formed a joint venture in 1982 to develop and produce a Stirling dish solar generating system. In this report, the six year development and testing program continued by the Southern California Edison Company (SCE) is described. Each Stirling dish module consists of a sun tracking dish concentrator developed by the MDAC and a Stirling engine driven power conversion unit (PCU) developed by USAB. The Stirling dish system demonstrated twice the peak and daily solar-to-electric conversion efficiency of any other system then under development. This system continues to set the performance standard for solar to electric systems being developed in the early 1990's. Test data are presented and used to estimate the performance of a commercial system. DOE

METHANE CHALLENGE OF HIGH PERFORMANCE MOLECULAR SIEVE OXYGEN CONCENTRATOR Interim Report, period ending Nov. 1992
Aaron M. Shakocius and George W. Miller Nov. 1993 8 p
(Contract F33615-92-C-0018)
(AD-A275155; AL/CF-PC-1993-0045) Avail: CASI HC A02/MF A01

The purpose of this work was to determine the ability of a high performance molecular sieve oxygen concentrator (MSOC) to remove methane while operating at high oxygen purity levels. This work was accomplished using a laboratory scale, four-bed, high performance MSOC which consisted of two primary beds containing OXYSIV-5 zeolite molecular sieve and two secondary beds containing Takeda 3A carbon molecular sieve. The concentrator operated at an inlet air pressure of 45 psia, a cycle time of 14 seconds, and a product flow rate of one standard liter per minute. Methane was injected into the MSOC inlet gas stream at levels up to approximately 5000 parts per million by volume (ppmv). Contaminant levels were allowed to reach steady-state and measured in the MSOC inlet, product, and exhaust gases with a Beckman model 402 hydrocarbon analyzer. The experimental results indicate the contaminant introduced into the MSOC inlet gas was separated and carried out with the exhaust gas. The injected methane was not detected in the product gas. The results indicate the high performance MSOC may be more capable of removing contaminants from the inlet gas stream than standard MSOC's, i.e., those containing only zeolite molecular sieve. Further experimental work with other contaminants is planned. DTIC

FOSSIL ENERGY BIOTECHNOLOGY: A RESEARCH NEEDS ASSESSMENT

Nov. 1993 302 p

(Contract DE-AC01-91ER-30156)

(DE94-004239; DOE/ER-30156/H1) Avail: CASI HC A14/MF A03

The Office of Program Analysis of the U.S. Department of Energy commissioned this study to evaluate and prioritize research needs in fossil energy biotechnology. The objectives were to identify research initiatives in biotechnology that offer timely and strategic options for the more efficient and effective uses of the Nation's fossil resource base, particularly the early identification of new and novel applications of biotechnology for the use or conversion of domestic fossil fuels. Fossil energy biotechnology consists of a number of diverse and distinct technologies, all related by the common denominator -- biocatalysis. The expert panel organized 14 technical subjects into three interrelated biotechnology programs: (1) upgrading the fuel value of fossil fuels; (2) bioconversion of fossil feedstocks and refined products to added value chemicals; and (3) the development of environmental management strategies to minimize and mitigate the release of toxic and hazardous petrochemical wastes. (Contract W-7405-eng-48)

(DE94-004472; UCRL-52000-93-8) Avail: CASI HC A03/MF A01

The Lawrence Livermore National Laboratory was established in 1952 to do research on nuclear weapons and magnetic fusion energy. Since then, other major programs have been added including laser fusion, and laser isotope separation, biomedical and environmental science, strategic defense and applied energy technology. These programs, in turn, require research in basic scientific disciplines, including chemistry and materials science, computer science and technology, engineering and physics. In this issue, Herald Brown, the Laboratory's third director and now counselor at the Center for Strategic and International Studies, reminisces about his years at Livermore and comments about the Laboratory's role in the future. Also an article on visualizing dynamic systems in three dimensions is presented. Researchers can use our interactive algorithms to translate massive quantities of numerical data into visual form and can assign the visual markers of their choice to represent three-dimensional phenomena in a two-dimensional setting, such as a monitor screen. Major work has been done in the visualization of climate modeling, but the algorithms can be used for visualizing virtually any phenomena. DOE

FUNDAMENTAL STACK AND SYSTEM ISSUES IN MOLTEN CARBONATE FUEL CELL DEVELOPMENT

M. C. Williams, E. L. Parsons, Jr., and M. J. Mayfield 1993 9 p Presented at the Annual Meeting of the American Institute of Chemical Engineers, St. Louis, MO, 7-12 Nov. 1993

(DE94-005960; DOE/METC-C/94/7118; CONF-931164-7) Avail: CASI HC A02/MF A01

Stack research and system issues in molten carbonate fuel cell (MCFC) technology development and commercialization are discussed within context of status of MCFC development and commercialization in US. Status of MCFC development is addressed. Major known fundamental stack research issues remaining for the MCFC technology are identified and discussed. The cathode remains a focal point of performance improvement and cost reduction. The various aspects of MCFC power plant network and systems issues are also addressed and discussed. These include cost, heat loss management, startup and shutdown modes, dynamic response, footprint, packaging and integration, parasitic power losses, pressurization, and reforming. Potential of MCFC networks is discussed. With the initial demonstration of full-area, full-height 250-kW to 2-MW MCFC power plants, the spatial configuration of the MCFC stacks into networks in the fuel cell power plant takes on importance for the first time. THE VIABILITY OF PHOTOVOLTAICS ON THE MARTIAN SURFACE

James R. Gaier and Marla E. Perez-Davis Mar. 1994 18 p Presented at the Case for Mars V Conference, Boulder, CO, 26-29 May 1993; sponsored by the Boulder Center for Science and Policy

(RTOP 583-02-21)

(NASA-TM-106478; E-8407; NAS 1.15:106478) Avail: CASI HC A03/MF A01

The viability of photovoltaics (PV) on the Martian surface may be determined by their ability to withstand significant degradation in the Martian environment. Probably the greatest threat is posed by fine dust particles which are continually blown about the surface of the planet. In an effort to determine the extent of the threat, and to investigate some abatement strategies, a series of experiments were conducted in the Martian Surface Wind Tunnel (MARSWIT) at NASA Ames Research Center. The effects of dust composition, particle size, wind velocity, angle of attack, and protective coatings on the transmittance of light through PV coverglass were determined. Both initially clear and initially dusted samples were subjected both to clear winds and simulated dust storms in the MARSWIT. It was found that wind velocity, particle size, and angle of attack are important parameters affecting occlusion of PV surfaces, while dust composition and protective coatings were not. Neither induced turbulence nor direct current biasing up to 200 volts were effective abatement techniques. Abrasion diffused the light impinging on the PV cells, but did not reduce total coverglass transmittance by more than a few percent. Author

CONFIGURATION AND PERFORMANCE OF THE INDIRECT-FIRED FUEL CELL BOTTOMED TURBINE CYCLE

P. L. Micheli, M. C. Williams, and E. L. Parsons, Jr. 1993 17 p Presented at the Annual Meeting of the American Institute of Chemical Engineers, St. Louis, MO, 7-12 Nov. 1993

(DE94-005961; DOE/METC-C/94/7117; CONF-931164-6) Avail: CASI HC A03/MF A01

The natural gas, indirect-fired fuel cell bottomed turbine cycle (NG-IFFC) is introduced as a novel power plant system for the distributed power and on-site markets in the 20-200 megawatt (MW) size range. The novel indirect-fired carbonate fuel cell bottomed turbine cycle (NG-IFCFC) power plant system configures the ambient pressure carbonate fuel cell with a gas turbine, air compressor, combustor, and ceramic heat exchanger. Performance calculations from ASPEN simulations present material and energy balances with expected power output. The results indicate efficiencies and heat rates for the NG-IFCFC are comparable to conventionally bottomed carbonate fuel cell steam bottomed cycles, but with smaller and less expensive components. MODAL ANALYSIS OF SOLAR PANELS USING BOUNDARY INTEGRAL EQUATIONS

H. T. Koelink, H. Schippers, J. J. Heijstek, and J. J. Derksen 3 Jul. 1992 16 p Presented at the Boundary Element International Conference, Seville, Spain, 3-6 Nov. 1992 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract NIVR-02003N)

(NLT-TP-92218-U; ETN-94-95582) Avail: Issuing Activity (European Space Agency (ESA))

The acoustic effects of the surrounding air on a harmonically vibrating solar panel in a test room are investigated. The dynamics of the solar panel are modeled by a differential equation for a harmonically vibrating plate. The force acting on the plate is caused by the jump in the acoustic pressure. The sound pressure is modeled by a boundary integral ansatz and these models are coupled by the acoustic coupling equation. This results in a perturbed eigenvalue problem which is solved approximately with respect to the perturbation parameter. The perturbation parameter is the ratio of the density of the air and the density of the solar panel. This analysis involves the solution of a hypersingular integral equation representing the pressure jump over the solar panel. The hypersingular integral equation is rewritten as a singular equation, which is numerically solved by a boundary element method. It involves the numerical evaluation of weakly singular and nearly weakly singular integrals. For an application the first and second order approximation is calculated (with respect to the perturbation parameter) for the eigenfrequency of the first bending mode of a solar panel in air. The second order approximation is in correspondence with the measured test room eigenfrequency. ESA

PHOTOVOLTAIC PERFORMANCE AND RELIABILITY WORKSHOP
L. Mrig, ed. 1993 504 p Presented at the Photovoltaic Performance and Reliability Workshop, Golden, CO, 8-10 Sep. 1993
(Contract DE-AC02-83CH-10093)
(DE94-000236; NREL/CP-410-6033; CONF-9309188) Avail: CASI HC A22/MF A04

This workshop was the sixth in a series of workshops sponsored by NREL/DOE under the general subject of photovoltaic testing and reliability during the period 1986-1993. PV performance and PV reliability are at least as important as PV cost, if not more. In the U.S., PV manufacturers, DOE laboratories, electric utilities, and others are engaged in the photovoltaic reliability research and testing. This group of researchers and others interested in the field were brought together to exchange the technical knowledge and field experience as related to current information in this evolving field of PV reliability. The papers presented here reflect this effort since the last workshop held in September, 1992. The topics covered include: cell and module characterization, module and system testing, durability and reliability, system field experience, and standards and codes. DOE

INTERNATIONAL COLLABORATIVE RESEARCH IN WIND TURBINE ROTOR AERODYNAMICS
D. A. Simms and C. P. Butterfield Dec. 1993 4 p Presented at the 13th Energy-Sources Technology Conference and Exhibition (ETCE) on Wind Energy, New Orleans, LA, 23-26 Jan. 1994
(Contract DE-AC02-83CH-10093)
(DE94-000244; NREL/TP-441-5810; CONF-940113-6) Avail: CASI HC A01/MF A01

Five organizations from four countries are collaborating to conduct detailed wind turbine aerodynamic test programs. Fullscale atmospheric testing will be conducted on turbines configured to measure aerodynamic forces on rotating airfoils. The purpose of these test programs is to come to a better understanding of the steady and unsteady aerodynamic behavior of wind turbine rotors, and provide information needed to build accurate aerodynamic models for design codes. Stall, dynamic inflow, yaw conditions, and tower effects all contribute to unknown aerodynamic responses. These unknown responses make it extremely difficult to produce cost-effective wind turbine designs. Turbines behave unexpectedly, experiencing power surges and higher fatigue loads than predicted. In order to evolve state-of-the-art wind turbine designs, these aerodynamic effects must be quantified and understood. This paper describes a coordinated international research effort that is underway to accelerate this key research area, and help develop a more thorough understanding of wind turbine aerodynamics. DOE

PV Cz SILICON MANUFACTURING TECHNOLOGY IMPROVEMENTS
T. Jester (Siemens Solar Industries, Camarillo, CA.) Jan. 1994 50 p
(Contract DE-AC02-83CH-10093)
(DE94-000248; NREL/TP-411-6010) Avail: CASI HC A03/MF A01

This report describes work performed under a 3-year contract to demonstrate significant cost reductions and improvements in manufacturing technology. The work focused on near-term projects for implementation in the Siemens Solar Industries Czochralski (Cz) manufacturing facility in Camarillo, California. The work was undertaken to increase the commercial viability and volume of photovoltaic manufacturing by evaluating the most significant cost categories and then lowering the cost of each item through experimentation, materials refinement, and better industrial engineering. The initial phase of the program concentrated on the areas of crystal growth; wafer technology; and environmental, safety, and health issues. DOE

N94-30604# Midwest Research Inst., Golden, CO.
LARGE-AREA TRIPLE-JUNCTION a-Si ALLOY PRODUCTION SCALE UP
R. Oswald (Solarex Corp., Newtown, PA.) and J. ODowd (Solarex Corp., Newtown, PA.) Jan. 1994 51 p
(Contract DE-AC02-83CH-10093)
(DE94-000249; NREL/TP-411-6047) Avail: CASI HC A04/MF A01

The objective of this subcontract over its three-year duration is to advance Solarex's photovoltaic manufacturing technologies, reduce its a-Si:H module production costs, increase module performance and expand the Solarex commercial production capacity. Solarex shall meet these objectives by improving the deposition and quality of the transparent front contact; optimizing the laser patterning process; scaling up the semiconductor deposition process; improving the back contact deposition; and scaling up and improving the encapsulation and testing of its a-Si:H modules. In the Phase 1 portion of this subcontract Solarex focused on scaling up components of the chemical vapor deposition system for deposition of the front contact; scaling up laser scribing techniques; triple-junction recipes for module production; and metal oxide back contacts. These efforts resulted in adopting portions of the manufacturing line to handle substrates larger than 0.37 sq m. DOE

N94-30605 Midwest Research Inst., Golden, CO.
THIN EFG OCTAGONS
J. P. Kalejs (Mobil Tyco Solar Energy Corp., Billerica, MA.) Jan. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract DE-AC02-83CH-10093)
(DE94-000257; NREL/TP-411-6046) Avail: Issuing Activity (Department of Energy (DOE))

Mobil Solar Energy Corporation currently practices a unique crystal growth technology for producing crystalline silicon sheet, which is then cut with lasers into wafers. The wafers are processed into solar cells and incorporated into modules for photovoltaic applications. The silicon sheet is produced using a method known as Edge-defined Film-fed growth (EFG), in the form of hollow eight-sided polygons (octagons) with 10 cm faces. These are grown to lengths of 5 meters and thickness of 300 microns, with continuous melt replenishment, in compact furnaces designed to operate at a high sheet area production area of 135 sq cm/min. The present Photovoltaic Manufacturing Technology (PVMaT) three-year program seeks to advance the manufacturing line capabilities of the Mobil Solar crystal growth and cutting technologies. If successful, these advancements will provide significant reductions in already low silicon raw material usage, improve process productivity, laser cutting throughput and yield, and so lower both individual wafer cost and the cost of module production. This report summarizes the significant technical improvements in EFG technology achieved in Phase 1 of this program. Technical results are reported for each of the three main program areas: (1) thin octagon growth (crystal growth) -- to reduce the thickness of the octagon to an interim goal of 250 microns during Phase 1, with an ultimate goal of achieving 200 micron thicknesses; (2) laser cutting -- to improve the laser cutting process, so as to produce wafers with decreased laser cutting damage at increased wafer throughput rates; and (3) process control and product specification -- to implement advanced strategies in crystal growth process control and productivity designed to increase wafer yields. DOE

THE DIRECT OBSERVATION OF ALKALI VAPOR SPECIES IN BIOMASS COMBUSTION AND GASIFICATION
R. J. French, D. C. Dayton, and T. A. Milne Jan. 1994 89 p
(Contract DE-AC02-83CH-10093)
(DE94-000262; NREL/TP-430-5597) Avail: CASI HC A05/MF A01

This report summarizes new data from screening various feedstocks for alkali vapor release under combustion conditions. The successful development of a laboratory flow reactor and molecular beam, mass spectrometer interface is detailed. Its application to several herbaceous and woody feedstocks, as well as a fast-pyrolysis oil, under 800 and 1100 C batch combustion, is documented. Chlorine seems to play a large role in the facile mobilization of potassium. Included in the report is a discussion of relevant literature on the alkali problem in combustors and turbines. Highlighted are the phenomena identified in studies on coal and methods that have been applied to alkali speciation. The nature of binding of alkali in coal versus biomass is discussed, together with the implications for the ease of release. Herbaceous species and many agricultural residues appear to pose significant problems in release of alkali species to the vapor at typical combustor temperatures. These problems could be especially acute in direct combustion fired turbines, but may be ameliorated in integrated gasification combined cycles. DOE

CRYSTALLINE-SILICON SOLAR CELL DEVELOPMENT SPONSORED BY THE US DEPARTMENT OF ENERGY
P. A. Basore 1993 4 p Presented at the 6th Sunshine Workshop on Crystalline Silicon Solar Cells, Tokyo, Japan, 18 Nov. 1993
(Contract DE-AC04-94AL-85000)
(DE94-003783; SAND-93-2744C; CONF-9311134-1) Avail: CASI HC A01/MF A01

Activities planned for the current fiscal year at Sandia National Laboratories include investigation of specific industrial cell processing issues using Sandia's Photovoltaic Device Processing Laboratory (PDFL), as well as several processing issues of general interest to companies using multicrystalline silicon. A significant and difficult goal for Sandia this year will be the fabrication of a 15% efficient prototype module using large-area multicrystalline cells. Sandia also provides primary funding for the University Center of Excellence in Photovoltaic Research and Education at the Georgia Institute of Technology. The National Renewable Energy Laboratory's (NREL's) plans for c-Si this fiscal year include continuation of the University Silicon Materials Research Program, which funds research at six universities to study the effect of cell processing on the properties of silicon materials. As the lead DOS laboratory for thin film technologies, NREL supports the development of thin film silicon cells by providing both funding and expertise. NREL also provides substantial funding to the PV industry through the PV Manufacturing Technology (PVMaT) initiative, some of which supports the development of c-Si cell technology either directly or indirectly. BIOLOGICAL CONVERSION OF SYNTHESIS GAS
R. Basu, K. T. Klasson, M. Takriff, E. C. Clausen, and J. L. Gaddy Sep. 1993 98 p
(Contract DE-FG21-90MC-27225)
(DE94-005815; DOE/MC-27225/3602) Avail: CASI HC A05/MF A02

The purpose of this research is to develop a technically and economically feasible process for biologically producing H2 from synthesis gas while, at the same time, removing harmful sulfur gas compounds. Six major tasks are being studied: culture development, where the best cultures are selected and conditions optimized for simultaneous hydrogen production and sulfur gas removal; mass transfer and kinetic studies in which equations necessary for process design are developed; bioreactor design studies, where the cultures chosen in the first task are utilized in continuous reaction vessels to demonstrate process feasibility and define operating conditions; evaluation of biological synthetic gas conversion under limiting conditions in preparation for industrial demonstration studies; process scale-up where laboratory data are scaled to larger-size units in preparation for process demonstration in a pilot-scale unit; and economic evaluation, where process simulations are used to project process economics and identify high cost areas during sensitivity analyses. THE EXECUTION OF WIND ENERGY PROJECTS 1986 - 1992 BETWEEN CHINA AERODYNAMICS RESEARCH AND DEVELOPMENT CENTRE (CARDC) AND THE AERONAUTICAL RESEARCH INSTITUTE OF SWEDEN (FFA)
He Dexin and Sven-Erik Thor Jun. 1993 35 p Sponsored by Swedish Board for Industrial and Technical Development
(FFA-TN-1993-19; ETN-94-95856) Avail: CASI HC A03/MF A01

The execution of the first phase agreement on wind energy projects, covering the period from 1986 to 1992, is summarized. The following are addressed: wind tunnel tests of a 2.2 m and 2.8 m diameter turbine, a 5.35 m turbine in stationary yaw operation, pressure measurements, wall interference correction, a 5.35 m diameter turbine under yaw control, visualization of the flow on the rotating blade. It was concluded that the yaw characteristics (including aerodynamic performance and control characteristics) and three dimensional flow of the wind turbine chosen as cooperation items have significant engineering application background and academic value. The results are applicable for medium as well as large size wind turbines and has a positive effect on the development of wind energy technology. ESA

N94-30946# Aeronautical Research Inst. of Sweden, Stockholm.
WIND TUNNEL TESTS OF A 5.3 M DIAMETER YAW CONTROLLED TURBINE
Eskil Ulen Sep. 1993 130 p Sponsored by Swedish Board for Industrial and Technical Development Prepared in cooperation with Chinese Aerodynamic Research and Development Center
(FFA-TN-1993-20; ETN-94-95857) Avail: CASI HC A07/MF A02

In order to meet the need for accurate wind turbine operating data from a variety of situations, a wind turbine was designed, built and tested. A description of the equipment and test results are given from a control point of view. The intention of the tests was to get a better understanding of the performance of a wind power station which from a system point of view is characterized by: two blades with fixed pitch angle, variable speed, yaw control of max rotor speed, hub with teeter, and induction generator. Some tests in stall region were also included. The intention was to get practical experiences by performing tests in a wind tunnel as realistically as possible. Of special interest are the following points: the load and aerodynamic torque of the blades with realistic values of rotor speed and yaw rate and angles; magnitude of teeter angle under yaw control; the required yaw motor torque; the coupling between yaw movements and tower lateral resonance ('fish tail' movement); disturbances, especially around

yaw axis caused by blade rotation; and the performance of a hub with teeter in stall region. A small complete wind power station with a realistic yaw servo was used. ESA

SPECIATION IN WATER AND SOIL: A LITERATURE REVIEW
Torbojorn Carlsson Mar. 1993 72 p
(ISSN 1235-0605)
(PB94-132388; VTT/RN-1455; ISBN-951-38-4348-3) Copyright Avail: CASI HC A04/MF A01

It is well known by now that the study of environmental pollution should be focused on the chemical forms of pollutants rather than on total concentrations. The need for more research on elemental speciation increases as pollutants are constantly released into the air, water, and soil. The work focuses mainly on heavy metal pollution in Finnish soil/water systems. The following topics are dealt with: (1) The geology and geochemistry of Finland, (2) pollution, (3) chemical time bombs (CTB's), (4) computer modeling, and (5) speciation. NTIS

USER-CENTERED GUIDELINES FOR ENVIRONMENTAL MANAGEMENT
D. R. Eike, J. A. Fox, and R. Dailey Aug. 1993 7 p Presented at the 5th International Conference on Human-Computer Interaction, Orlando, FL, 8-13 Aug. 1993
(Contract DE-AC06-76RL-01830)
(DE94-004313; PNL-SA-22420; CONF-9308124-2) Avail: CASI HC A02/MF A01

Environmental management requirements facing U.S. Department of Energy (DOE) facilities are detailed, complex, and often subject to rapid change. DOE's Office of Environmental Guidance, RCRA/CERCLA Division (EH-231), is responsible for developing and issuing guidance to assist DOE facilities in interpreting and complying with federal, state, and local requirements. Recognizing the potential for computerization of the guidance, EH-231 requested that Pacific Northwest Laboratory (PNL) develop an approach for preparing automated guidance. The approach developed by PNL, termed 'user-centered guidance,' combines participatory design and traditional rapid prototyping techniques to produce a new form of environmental guidance that emphasizes the user's needs. This paper describes the objectives, processes, and current status of this effort. DOE

N94-28463# North Dakota Univ., Grand Forks. Energy and Environmental Research Center.
CATALYTIC FABRIC FILTRATION FOR SIMULTANEOUS NO(x) AND PARTICULATE CONTROL
G. F. Weber, S. R. Ness, D. L. Laudal, and G. E. Dunham Aug. 1993 20 p
(Contract DE-AC22-90PC-90361)
(DE94-001660; DOE/PC-90361/T11) Avail: CASI HC A03/MF A01

The University of North Dakota Energy and Environmental Research Center (EERC), Owens-Corning Fiberglas Corporation (OCF), and Raytheon Engineers and Constructors (RE&C), are conducting research to develop a catalytic fabric filter (CFF) for simultaneous NO(x) and particulate control. Advances at OCF have shown that a high-activity catalyst can be applied to a high-temperature woven glass cloth resulting in a fabric filter material that can operate at temperatures higher than commercially available, coated glass fabric. The NO(x) is removed by catalytic reduction with ammonia to form nitrogen and water. The catalyst employed at this time is vanadium/titanium, but the exact catalyst composition and the unique method of applying the catalyst to high-temperature glass fabric are the property of OCF. Other catalyst options are being evaluated by OCF in order to improve catalyst performance and minimize catalyst cost. Bench-scale experimental results have shown that over 90% NO(x) removal can be achieved, that the catalyst/fabric has promising self-abrasion characteristics, and that the potential exists for substantially reduced cost compared to conventional SCR/fabric filtration technology. However, development of the technology requires further evaluation of air-to-cloth ratio effects, ammonia slip, SO2 oxidation to SO3, temperature cycling, catalyst-coated fabric preparation, fuel impacts, fabric cleaning (reverse-gas versus pulse-jet), catalyst life (poisoning and resistance to erosion), and filter performance/life (particulate control, differential pressure, and durability). DOE

DEVELOPMENT OF THE INTEGRATED ENVIRONMENTAL CONTROL MODEL: PERFORMANCE MODELS OF SELECTIVE CATALYTIC REDUCTION NO(x) CONTROL SYSTEMS
H. C. Frey Jul. 1993 50 p
(Contract DE-AC22-92PC-91346)
(DE94-002151; DOE/PC-91346/3) Avail: CASI HC A03/MF A01

This report concerns the Integrated Environmental Control Model (IECM) created and enhanced by Carnegie Mellon University (CMU) for the US Department of Energy's Pittsburgh Energy Technology Center (DOE/PETC). The IECM provides a capability to model various conventional and advanced processes for controlling air pollutant emissions from coal-fired power plants before, during, or after combustion. The principal purpose of the model is to calculate the performance, emissions, and cost of power plant configurations employing alternative environmental control methods. The model consists of various control technology modules, which may be integrated into a complete utility plant in any desired combination. In contrast to conventional deterministic models, the IECM offers the unique capability to assign probabilistic values to all model input parameters, and to obtain probabilistic outputs in the form of cumulative distribution functions indicating the likelihood of different costs and performance results. GLOBAL CHANGE RESEARCH: SUMMARIES OF RESEARCH IN FY 1993
Oct. 1993 230 p
(DE94-003150; DOE/ER-0597T) Avail: CASI HC A11/MF A03

This document describes the activities and products of the Global Research Program in FY 1993. This publication describes all of the projects funded by the Environmental Sciences Division of DOE under annual contracts, grants, and interagency agreements in FY 1993. Each description contains the project's title; its 3-year funding history (in thousands of dollars); the period over which the funding applies; the name(s) of the principal investigator(s); the institution(s) conducting the projects; and the project's objectives, products, approach, and results to date (for most projects older than 1 year). Project descriptions are categorized within the report according to program areas: climate modeling, quantitative links, global carbon cycle, vegetation research, ocean research, economics of global climate change, education, information and integration, and NIGEC. Within these categories, the descriptions are grouped alphabetically by principal investigator. Each program area is preceded by a brief text that defines the program area, states its goals and objectives, lists principal research questions, and identifies program managers. DOE

GLOBAL ATMOSPHERIC AND OCEAN MODELING ON THE CONNECTION MACHINE
S. R. Atlas (Thinking Machines Corp., Cambridge, MA.) 1993 12 p Presented at the North Atlantic Treaty Organization/Advanced Study Institute (NATO/ASI) Workshop in High Performance Computing in Geosciences, Chamouix, France, 21-25 Jun. 1993
(Contract W-7405-eng-36)
(DE94-003930; LA-UR-93-4224; CONF-9306285-1) Avail: CASI HC A03/MF A01

This paper describes the high-level architecture of two parallel global climate models: an atmospheric model based on the Geophysical Fluid Dynamics Laboratory (GFDL) SKYHI model, and an ocean model descended from the Bryan-Cox-Semtner ocean general circulation model. These parallel models are being developed as part of a long-term research collaboration between Los Alamos National Laboratory (LANL) and the GFDL. The goal of this collaboration is to develop parallel global climate models which are modular in structure, portable across a wide variety of machine architectures and programming paradigms, and provide an appropriate starting point for a fully coupled model. Several design considerations have emerged as central to achieving these goals. These include the expression of the models in terms of mathematical primitives such as stencil operators, to facilitate performance optimization on different computational platforms; the isolation of communication from computation to allow flexible implementation of a single code under message-passing or data parallel programming paradigms; and judicious memory management to achieve modularity without memory explosion costs. LOCAL MEASUREMENT OF TROPOSPHERIC HO(x) Final Report
David R. Crosley Hampton, VA NASA Feb. 1994 79 p Sponsored by NASA. Langley Research Center and NSF
(RTOP 464-54-03-70)
(NASA-CP-3245; L-17370; NAS 1.55:3245) Avail: CASI HC A05/MF A01

In March of 1992 a workshop sponsored by NASA and NSF was held at SRI International to assess the current ability to measure atmospheric OH and HO2. The measurement techniques reviewed during the workshop for detection of OH included five laser-induced fluorescence schemes, five laser-based adsorption techniques, and four non-laser methods. Six instruments or instrument concepts for HO2 detection, including chemical amplification, conversion to OH with subsequent OH detection, or direct spectroscopic detection of the HO2 were also discussed. The conclusions from the workshop identify several measurement techniques for OH and HO2 that are ready for field tests. These have the ability to measure the radicals with sufficient sensitivity and accuracy to form meaningful comparison with atmospheric model predictions. The workshop conclusions also include recommendations for informal and formal intercomparison protocols. For individual titles, see N94-28588 through N94-28608.

TWO-PHOTON/LASER-INDUCED FLUORESCENCE (TP/LIF) SENSOR Abstract Only
John D. Bradshaw *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)
Avail: CASI HC A01/MF A01

The Two-Photon/Laser-Induced Fluorescence (TP/LIF) technique is based on the stepwise excitation of the OH transitions, X(exp 2)II, v(exp '') = 0 yields X(exp 2)II, v(exp '') = 1 (lambda = 2.9 microns) and X(exp 2)II v(exp '') = 1 yields A(exp2)Sigma, v' = 0 (lambda = 345 nm) with background free fluorescence monitoring of the A(exp 2)Sigma, v' = 0 yields X(exp 2)II, v(exp '') = 0 transition near 309 nm. This technique has awaited the advent of a suitable mid-infrared (2.9 microns) laser source. Turnable mid-IR lasers now exist that are capable of meeting the specifications required of a high sensitivity TP/LIF OH sensor. Author

Just as in the method of Hard and O'Brien, ambient air is pulled through an approximately 1 mm diameter inlet into a detection chamber that is maintained at a pressure of 2.4 torr. The ambient air stream travels through the detection chamber with a velocity of greater than 100 m sec(exp -1) in a narrow stream, constrained by the addition of an inert gas flow (0.4 torr). The OH molecule is both excited and detected in the A(exp 2)Sigma (v' = 0) yields X(exp 2)II (v'' = 0) transition at 308 nm. Light from a copper vapor-pumped dye laser (rep. rate = 10kHz; pulse length = 20 ns; linewidth = .1 cm(exp -1), and average power = 15 mW), resonant with the Q(sub 1)(3) transition, is multipassed through a White cell and intercepts the air stream as 24 non-overlapping 2mm by 5mm beams. A fast microchannel plate detector is turned off during the laser pulse to prevent saturation of the detector due to Rayleigh and chamber scattering. It is turned on 30-100 nsec after the end of the laser pulse for 300 ns to collect resonance fluorescence from OH. HO2 is detected by chemical conversion to OH by reaction with reagent NO, followed by OH detection. Both the detection sensitivity and the inlet characteristics must be understood for any in situ instrument. For the calibration of the detection sensitivity, OH is produced quantitatively by the fast H + NO2 yields OH + NO reaction in a low pressure, flowing discharge tube connected to the detection chamber. The inlet transmission of OH inlet is calibrated separately. Derived from text

In the measurement of tropospheric HO we have employed three low-pressure laser-excited fluorescence (LEF) experimental systems. These instruments operate by expanding the ambient air flow via a nozzle, followed by transit down a flowtube through a detection region traversed by the excitation laser beam. This sampling method we named FAGE (fluorescence assay with gas expansion). The instruments employed a hydrocarbon reagent, added below the nozzle, to remove HO for background measurement. In the second and third instruments, air sampling via parallel nozzles and tubes, with reagent addition alternating between two channels, permitted continuous signal measurement with simultaneous measurement of background. The first two instruments (FAGE1 and FAGE2) used 282 nm HO excitation by frequency-doubled tunable dye lasers, pumped by pulsed Nd:YAG lasers at 10-30 Hz repetition rate. The third instrument (FAGE3) uses 308 nm excitation in which the dye laser is pumped by a copper vapor laser, pulsed at 5600 Hz. Author

Laser-induced fluorescence (LIF) spectroscopy is a highly sensitive method for the direct in situ measurement of hydroxyl concentrations in the atmosphere. Its sensitivity and selectivity relies on the intense discrete UV-absorption lines of OH which are strongest around 282nm and 308nm. We have developed a LIF-instrument based on the low-pressure experiment (FAGE). However, we use 308nm instead of 282nm as excitation wavelength for OH, a concept that is also pursued by other groups. One advantage of the longer excitation wavelength is the higher detection sensitivity due to the about 6 times larger effective OH-fluorescence cross-section. Moreover, the O3/H2O-interference (OH self-generation by the laser) is about a factor of 200 smaller at 308nm than at 282nm. This keeps the interference level well below the projected detection limit of 10(exp 5) OH/cm(exp 3). Atmospheric HO2-radicals are detected by chemical conversion of HO2 into OH with NO. Author

The Harvard ER-2 OH instrument is scheduled to be integrated into the NASA ER-2 high altitude aircraft ozone payload in August 1992. Design and fabrication is presently underway. This experiment is a descendant of a balloon borne instrument designed and built in the mid-1980s. The ER-2 instrument is being designed to measure OH and HO2 as part of the NASA ozone payload for the investigation of processes controlling the concentration of stratospheric ozone. Although not specifically designed to do so, it is hoped that valid measurements of OH and HO2 can be made in the remote free troposphere with this instrument. Author

JPL FOURIER TRANSFORM ULTRAVIOLET SPECTROMETER Abstract Only

R. P. Cageao, R. R. Friedl, Stanley P. Sander, and Y. L. Yung *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

The Fourier Transform Ultraviolet Spectrometer (FTUVS) is a new high resolution interferometric spectrometer for multiple-species detection in the UV, visible and near-IR. As an OH sensor, measurements can be carried out by remote sensing (limb emission and column absorption), or in-situ sensing (long-path absorption or laser-induced fluorescence). As a high resolution detector in a high repetition rate (greater than 10 kHz) LIF system, OH fluorescence can be discriminated against non-resonant background emission and laser scatter, permitting (0, 0) excitation.

ABSOLUTE DETERMINATION OF LOCAL TROPOSPHERIC OH CONCENTRATIONS Abstract Only

Wolfgang Armerding and Franz-Josef Comes *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Long path absorption (LPA) according to Lambert Beer's law is a method to determine absolute concentrations of trace gases such as tropospheric OH. We have developed a LPA instrument which is based on a rapid tuning of the light source which is a frequency doubled dye laser. The laser is tuned across two or three OH absorption features around 308 nm with a scanning speed of 0.07 cm(exp -1)/microsecond and a repetition rate of 1.3 kHz. This high scanning speed greatly reduces the fluctuation of the light intensity caused by the atmosphere. To obtain the required high sensitivity the laser output power is additionally made constant and stabilized by an electro-optical modulator. The present sensitivity is of the order of a few times 10(exp 5) OH per cm(exp 3) for an acquisition time of a minute and an absorption path length of only 1200 meters so that a folding of the optical path in a multireflection cell was possible leading to a lateral dimension of the cell of a few meters. This allows local measurements to be made. Tropospheric measurements have been carried out in 1991 resulting in the determination of OH diurnal variation at specific days in late summer. Comparison with model calculations have been made. Interferences are mainly due to SO2 absorption. The problem of OH self generation in the multireflection cell is of minor extent. This could be shown by using different experimental methods. The minimum-maximum signal to noise ratio is about 8 x 10(exp -4) for a single scan. Due to the small size of the absorption cell the realization of an open air laboratory is possible in which by use of an additional UV light source or by additional fluxes of trace gases the chemistry can be changed under controlled conditions allowing kinetic studies of tropospheric photochemistry to be made in open air. Long path Differential Optical Absorption Spectroscopy (DOAS) using a picosecond UV laser as a light source was developed in our institute. Tropospheric OH radicals are measured by their rotational absorption lines around 308 nm. The spectra are obtained using a high resolution spectrograph. The detection system has been improved over the formerly used optomechanical scanning device by application of a photodiode array which increased the observed spectral range by a factor of 6 and which utilizes the light much more effectively leading to a considerable reduction of the measurement time. This technique provides direct measurements of OH because the signal is given by the product of the absorption coefficient and the OH concentration along the light path according to Lambert-Beers law. No calibration is needed. Since the integrated absorption coefficient is well known the accuracy of the measurement essentially depends on the extent to which the OH absorption pattern can be detected in the spectra. No interference by self generated OH radicals in the detection lightpath has been observed. The large bandwidth (greater than 0.15 nm) and the high spectral resolution (1.5 pm) allows absolute determination of interferences by other trace gas absorptions. The measurement error is directly accessible from the absorption-signal to baseline-noise ratio in the spectra. The applicability of the method strongly depends on visibility. Elevated concentrations of aerosols lead to considerable attenuation of the laser light which reduces the S/N-ratio. In the moderately polluted air of Julich, where we performed a number of OH measurement spectra. In addition absorption features of unidentified species were frequently detected. A quantitative deconvolution even of the known species is not easy to achieve and can leave residual structures in the spectra. Thus interferences usually increase the noise and deteriorate the OH detection sensitivity. Using diode arrays for sensitive absorption measurements some specific problems of those detectors have to be solved experimentally (i.e. fixed pattern noise, dark signal noise, nonuniform efficiency of individual elements, spatial sensitivity variations). In order to improve the low spatial resolution we performed laboratory studies using a multiple reflection cell to convert the long path technique to a real in situ point measurement. Under the conditions of field experiments in Julich residual absorbance signals at present are about 1.5x10(exp -4) corresponding to an OH detection sensitivity of 2x10(exp 6) OH/cm(exp 3) using a light path of 5.8 km. Total integration times for one measurement point vary between a few minutes and an hour. Author

MEASUREMENT OF TROPOSPHERIC OH BY LASER LONG-PATH ABSORPTION SPECTROSCOPY Abstract Only

Michael Kraft and D. Perner *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)
Avail: CASI HC A01/MF A01

OH-radicals are measured by laser long-path absorption spectroscopy. A tunable Nd:YAG/dye laser system provides broadbanded light at 308 nm. The beam is expanded to 0.3 m and pointed to an array of retroreflectors placed at a distance of 2800 m. The returning beam is separated from the outgoing beam and focused into a spectrometer of 0.3 pm resolution. A 1024 element diode array is used as a detector. The signal is digitized by a 14 bit analog to digital converter. The ultimate aim is a detection limit of 10(exp 5) molecules cm(exp -3) of OH. However the measurements in 1991 allowed only the recognition of OH absorptions corresponding to 3 x 10(exp 6) OH cm(exp -3) with a signal to noise ratio of two. Improvements of the instrument are under way. The advantages of the DOAS method are: the accuracy of detection is guaranteed because loss of OH radicals within the device is avoided, the rate of OH production by the device is negligible, and absorptions of other trace gases could be corrected for; and the calibration procedure for the device is fast and easy. The disadvantages of the system are: time resolution is about minutes because about ten spectra had to be added to keep the noise level down, the OH concentration is averaged along the whole light path, weight (500 kg) and size (4x4 m) of the device; and approximately 10 l/min of coolant and supply of 8 kW electrical power are necessary. Intracavity laser spectroscopy (ILS) has been demonstrated to be useful for measuring extremely weak absorption produced by gases in air. ILS is based on the observation that when there are spectrally narrow losses within the cavity of a broadband laser, the laser output has corresponding spectral holes where the laser oscillation is partially quenched. The depth of the laser output dips can be enhanced by a factor of 10(exp 5) over the depth of the initial cavity loss, and absorptivities of 10(exp -8) cm(exp -1) have been measured in lasers only one meter long. With ILS, one can achieve in a compact space a spectral contrast that would otherwise require kilometers of pathlength. ILS systems typically use quasi-continuous wave dye lasers operating close to threshold. The pump laser is modulated from just below to just above the threshold level for the dye laser, and the dye laser output is spectroscopically observed during a well defined time interval after the onset of lasing (the generation time). The spectral contrast of an intracavity absorber is equivalent to that produced by absorption through a path length equal to the generation time multiplied by the speed of light (assuming the cavity is completely filed with the absorber) up to some limiting time. Thus, if one measures the spectrum after 33 microseconds, the effective path length is 10,000 meters.

Recent research has shown that certain polymethine dyes can be detected at ultratrace levels (greater than or equal to 6x10(exp -14) M) in solution by fluorimetry. These detection limits are possible because of the inherent sensitivity of fluorescence techniques, because the dyes fluoresce in the near infrared region where background interference is negligible, and because powerful infrared diode lasers are now available to improve the signal to noise ratio. Other work has shown that the hydroxyl radical destroys the ability of polymethine dyes to fluoresce. These observations form the basis for a new hydroxyl radical detector that is essentially a fluorometric titrator. Theoretically, the detector should show an acceptable sensitivity and response time. Assuming that the atmospheric HO concentration is about 10(exp -11) moles m(exp -3) (i.e. 10(exp 6) molecules cm(exp -3)), then 10 L of air 'titrated' with 20 mL of 10(exp -11) M dye solution (an easily detected concentration) should result in a drop in the fluorescent signal of 50 percent - a readily detectable change. At a flow rate of 3 L min(exp -1) the sampling time would be 3 minutes. The biggest potential problem is selectivity: other oxidants may also cause the fluorescence signal to be lost. The chemistry of polymethine dyes has not been studied in detail and so no quantitative data are available. However, a survey of the literature suggests that in general HO should react up to six orders of magnitude faster than HO2 and other radicals such as RO2 and RO. It should also react much more rapidly than H2O2 and O3. Thus it may be possible to discriminate kinetically against potential interfering substances. It was shown in the laboratory that 10(exp -4) M H2O2 has little effect on the absorption spectrum of the dye IR125 over a period of hours but that the band at 780 nm is slowly lost in water over a period of days even under argon in the dark. By contrast, DMSO solutions of IR125 are stable. Author

ION-ASSISTED TROPOSPHERIC OH MEASUREMENT TECHNIQUE Abstract Only
Fred L. Eisele *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)
Avail: CASI HC A01/MF A01

The present technique measures atmospheric OH concentrations by first titrating OH into isotopically labeled H2(exp 34)SO4 by a series of gas phase reactions in an effectively wall-less flow tube reactor on a time-scale which is short in comparison to the OH lifetime. The gas phase H2SO4 concentration is then determined by reacting it with NO3(-)(center dot)HNO3 ions in a flow tube, and subsequently measuring the resulting (HSO4(-))/(NO3(-)) ion ratio. Since the determination of H2SO4 concentration does not depend on the measurement of an absolute photon flux or chemical concentration but rather only on the relative concentration measurement of two fairly similar mass ions in conjunction with a fixed reaction time and reaction rate coefficient, no in-field calibration technique should be required. The ion-assisted OH measurement technique provides a concentration measurement about once each 10 to 20 seconds and had a detection sensitivity less than or equal to 1 x 10(exp 5) molecules/cu cm (2 standard deviations) with an integration time of 5 minutes during the past field study. Typically, the total background signal level is in the low 10(exp 6) molecule/cu cm range with the scatter in this background (or background noise in 5 minutes) in the mid 10(exp 4) molecules/cu cm range. THE ACTIVE TITRATION METHOD FOR MEASURING LOCAL HYDROXYL RADICAL CONCENTRATION Abstract Only

Michele Sprengnether and Ronald G. Prinn *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

We are developing a method for measuring ambient OH by monitoring its rate of reaction with a chemical species. Our technique involves the local, instantaneous release of a mixture of saturated cyclic hydrocarbons (titrants) and perfluorocarbons (dispersants). These species must not normally be present in ambient air above the part per trillion concentration. We then track the mixture downwind using a real-time portable ECD tracer instrument. We collect air samples in canisters every few minutes for roughly one hour. We then return to the laboratory and analyze our air samples to determine the ratios of the titrant to dispersant concentrations. The trends in these ratios give us the ambient OH concentration from the relation: dlnR/dt = -k(OH). A successful measurement of OH requires that the trends in these ratios be measureable. We must not perturb ambient OH concentrations. The titrant to dispersant ratio must be spatially invariant. Finally, heterogeneous reactions of our titrant and dispersant species must be negligible relative to the titrant reaction with OH. We have conducted laboratory studies of our ability to measure the titrant to dispersant ratios as a function of concentration down to the few part per trillion concentration. We have subsequently used these results in a gaussian puff model to estimate our expected uncertainty in a field measurement of OH. Our results indicate that under a range of atmospheric conditions we expect to be able to measure OH with a sensitivity of 3x10(exp 5) cm(exp -3). In our most optimistic scenarios, we obtain a sensitivity of 1x10(exp 5) cm(exp -3). These sensitivity values reflect our anticipated ability to measure the ratio trends. However, because we are also using a rate constant to obtain our (OH) from this ratio trend, our accuracy cannot be better than that of the rate constant, which we expect to be about 20 percent.

PEROXY RADICAL MEASUREMENTS WITH NCAR'S CHEMICAL AMPLIFIER Abstract Only

Christopher Cantrell, Richard Shetter, and Jack G. Calvert *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

The present NCAR instrument for HO2/RO2 measurements has been described previously. It is based on the reactions involving HO2, RO2, and HO radicals with CO and NO. Since (HO2) + (RO2) + (HO) is much greater than (HO) for most atmospheres, it is useful as a peroxy radical detector. Operation of the instrument depends on the creation of a chemical chain reaction which is initiated as HO2 and RO2 radicals in ambient air encounter added NO gas; this forms an NO2 molecule and an HO or RO radical: HO2(RO2) + NO yields HO(RO) + NO2. RO radicals react relatively efficiently with O2 to form an HO2 radical, and subsequently an HO-radical, by reaction with NO. CO gas added to the reaction chamber during part of the operating cycle, recycles the HO to HO2; HO + CO (+O2) yields HO2 + CO2. The reaction sequence may form several hundred NO2 molecules per HO2 (RO2) originally present, before chain termination occurs. The added CO is replaced by N2 addition periodically so that the chain reaction is suppressed, and a 'blank' signal resulting from NO2, O3 and possibly other NO2-forming species (non-chain processes) in ambient air is recorded. The difference between the signal with and without CO is proportional to the peroxy radical concentration. The NO2 produced is monitored using a sensitive luminol chemiluminescence detector system. In the NCAR instrument the length of the amplification chain is determined using a stable source of HO2 radicals (H2O2 thermal decomposition); the ratio of the signal seen with CO present to that with N2 present gives the sensitivity of the instrument to HO2 (molecules of NO2 formed/peroxy radical). The instrument is automated to carry out in hourly repeated cycles: (1) chain length determination; (2) NO2 calibration; and (3) linearity check on the response of signals. One minute averages of signals are normally recorded. The sensitivity of the instrument to detect peroxy radicals is in the pptv range. The present instrument has operated continuously (24 hr/day) in the field studies which extended over a period of several weeks. The major advantages of this instrument are as follows: (1) its relative simplicity; (2) low power requirements; and (3) its rapid response to all types of peroxy radicals--HO2, CH3O2 and the higher alkyl and acyl peroxy radicals; however not all RO2 species generate HO2 radicals with perfect efficiency and hence have somewhat lower response/molecule than HO2 radicals.

THE RADICAL AMPLIFIER Abstract Only

D. R. Hastie *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

The radical amplifier as a method for measuring radical concentrations in the atmosphere has received renewed attention lately. In principle, it can measure the total concentration of HO(x) and RO(x) radicals by reacting ambient air with high concentrations of CO (3-10 percent) and NO (2-6 pprnv), and measuring the NO2 produced.

AN IMPROVED METHOD OF MEASURING TROPOSPHERIC NO2, NO3, HO2, AND RO2 BY MATRIX ISOLATION AND ELECTRONIC SPIN RESONANCE (MIESR) Abstract Only

In its Local Measurement of Tropospheric HO(x) 1 p(SEE N94-28587 08-45) Feb. 1994 (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

The MIESR method consists of two steps (1) collection of the radicals present in the ambient air at 77K in a polycrystalline D2O matrix and (2) identification and quantification of the different radicals in the laboratory by Electron Spin Resonance spectroscopy. In step (1), the sampling efficiency for sampling NO2 and RO2 was determined to be greater than or equal to 95 percent, with a measured accuracy of plus or minus 5 percent. In step (2), after collection, the samples are maintained at 77 K and spectra are recorded in the laboratory using a standard 9.5 GHz ESR system (Varian E-line). About 50 individual scans of each spectrum are recorded and digitally averaged in order to improve the signal-to-noise ratio. The ESR-spectra are analyzed with a recently developed numerical procedure which was demonstrated to allow speciation of NO2, NO3, HO2, CH3C(O)O2, and the sum of the alkylperoxy radicals. The detection limit is 5ppt for HO2, RO2, and NO2 and 3ppt for NO3 due to its narrower ESR-linewidth.

NEAR-IR DIODE LASER ABSORPTION FOR MEASUREMENT OF TROPOSPHERIC HO2 Abstract Only

Alan C. Stanton *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)

Avail: CASI HC A01/MF A01

The possibility of using tunable lead salt diode lasers in the infrared for measurement of tropospheric HO2 has been frequently considered. Although the sensitivity of diode laser absorption has been improved through the use of high frequency detection techniques, nature has been unkind in that the HO2 absorption cross sections are weak. Even using the most optimistic assumptions about attainable path length and detectable absorbance, measurement of tropospheric HO2 by diode laser absorption in the mid-IR appears marginal. A possible alternative method for measuring HO2 is by absorption at near-infrared wavelengths. Several absorption

bands of HO2 occur in the wavelength region between 1.2 and 1.6 micron due to electronic transitions and overtones of the fundamental vibrational modes. InGaAsP diode lasers operate in this wavelength region and can be used for high resolution spectroscopy in a manner analogous to the lead salt lasers. A diode laser system in the near-IR offers some advantages. Author

HO2 DETECTION BY NEAR INFRARED ABSORPTION USING TUNABLE DIODE LASERS Abstract Only
David Nelson and Mark S. Zahniser *In* SRI International Corp., Local Measurement of Tropospheric HO(x) Feb. 1994 1 p (For primary document see N94-28587 08-45)
Avail: CASI HC A01/MF A01

The strongest absorption lines are in the v sub 2 vibrational band around 1400/cm; several near-coincident line pairs in this region provide max linestrengths of 1.2 x 10 exp -20 sq. cm/(molecule*cm). High Frequency wavelength modulation coupled with sweep integration were used to minimize noise and maintain spectral discrimination. Reduced pressure sampling was performed using supersonic nozzle and an aerodynamic flow cell to minimize residence time and wall losses of radicals. The astigmatic mirror design provides pathlengths up to 200 m in volume of 3 liters with minimal optical interference fringes; longer pathlengths are possible. The detection limit depends on pathlength and minimum fractional absorptions.

SURVEY ON EFFECTS OF PETROLEUM SUBSTITUTION ENERGY UTILIZATION ON THE GLOBAL ENVIRONMENT
Mar. 1993 199 p
(DE94-732339; NEDO-P-9228) Avail: CASI HC A09/MF A03

Investigations/analyses are conducted on objectives, policies and measures of the world's major countries in relation to the Framework Convention on Climate Change, particularly CO2 emission. The problem on climate change is a global issue, and the CO2 emission control is directly connected with energy consumption closely related to national economies. Therefore, interests conflict between the north and the south, and among the developed countries. The U.S. Clinton administration is beginning to show a more positive attitude than before, and aims to take the most realistic measures such as the proposed new Btu tax in the developed countries. As for EC, whether or not CO2 stabilization targeted in 2000 is made possible depends on how much Germany can achieve the target. British strong opposition attitude toward the carbon/energy taxes presents a question to the target to be attained by 2000. Hereafter, tie-ups jointly taken for CO2 control measures between developed countries and developing countries are expected to be a matter of increasing importance. DOE

ENVIRONMENTAL COMPLIANCE ASSESSMENT SYSTEM (ECAS) Final Report
David A. Krooks and Tina M. Hurt Dec. 1993 226 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275549; CERL-SR-EC-94/04) Avail: CASI HC A11

The U.S. Army has adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Major Army Commands (MACOM's) must conduct comprehensive environmental assessments at all installations on a 4-year cycle and conduct a mid-cycle internal assessment. Because each MACOM developed a separate system, the Army mandated a unified, Army-wide assessment mechanism, which combines Federal, Department of Defense (DOD), and Army environmental regulations; good management practices; and risk-management issues into a series of checklists that show requirements and specific items or operations to review. Each protocol lists a point of contact to help assessors review checklist items. The Worldwide Environmental Compliance Assessment System (ECAS) manual incorporates checklists from USEPA and from private industry. It integrates information from the Overseas Environmental Baseline Guidance Document (OEBGD). Worldwide ECAS includes pertinent information from Army Regulations and DOD Directives and Instructions and cites management practices for an overall environmental review. The ECAS JAPAN supplement incorporates Japanese legislation, regulations, and suggested management practices. It was developed for use in conjunction with the Worldwide ECAS manuals (USACERL SR-EC-93/03) and is updated continually to address changes in Japanese laws and regulations. DTIC

ENVIRONMENTAL COMPLIANCE ASSESSMENT AND MANAGEMENT SYSTEM PROGRAM (ECAMP). US AIR FORCE EUROPEAN ECONOMIC COMMUNITY (EEC) Final Report
Donna J. Schell and Tina M. Beckler Sep. 1993 290 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 9201)
(AD-A275593; CERL-SR-EC-93/12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In response to the growing number of environmental laws and regulations worldwide, the Air Force adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Beginning in 1984, the U.S. Army Construction Engineering Research Laboratories, in cooperation with the Air Force Engineering and Services Center, began research on ECAMP. Federal, Department of Defense (DOD), and Air Force environmental regulations, along with documentation of good management practices and risk-management information, were integrated into a series of checklists that show (1) legal requirements, and (2) specify items or operations to review. Assessment protocols list a point of contact to help assessors review the checklists as effectively as possible. The Worldwide ECAMP incorporates existing USEPA and private industry checklists, and integrates the DOD Overseas Environmental Baseline Guidance Document (OEBGD), published in October 1992. Additionally, Worldwide ECAMP includes pertinent information from Air Force Regulations, DOD Directives and Instructions, and cited good management practices for overall environmental review. The EEC manual supplements Worldwide ECAMP with existing EEC directives, regulations, and decisions and suggested management practices. The program was tested at Aviano Air Force Bass (AFB), Italy in November 1992 and Soesterberg AFB, Netherlands in June 1993. DTIC

ENVIRONMENTAL REVIEW GUIDE FOR OPERATIONS (ERGO) Final Report
Donna J. Schell and Tina M. Beckler Apr. 1993 810 p
(AD-A275611; CERL-SR-EC-93/10) Avail: CASI HC A99/MF A10

In response to the growing number of environmental laws and regulations worldwide, the Corps of Engineers adopted an environmental compliance program that identifies compliance problems before they are cited as violations by the U.S. Environmental Protection Agency (USEPA). Beginning in 1989, the U.S. Army Construction Engineering Research Laboratories, in cooperation with a Steering Committee representing the Corps of Engineers, began research on ERGO. The concept was to combine Code of Federal Regulations (CFR's) and Engineering Regulations, along with good management practices and risk-management information, into a series of checklists that show (1) legal requirements and (2) which specific items or operations to review. Each assessment protocol lists a point of contact to help assessors review the checklists as effectively as possible. The ERGO manual incorporates CFR's and Engineering Regulations as well as suggested management practices. The manual was tested at Nashville, Tennessee in 1990. After this evaluation, the first ERGO manual was printed and distributed to the environmental coordinators at Army Corps of Engineers' Facilities located in the United States. Since this initial printing, the ERGO manual has been updated and revised annually. The manual is continually updated to address new environmental compliance laws and regulations. DTIC

THE EUROPEAN COMMUNITY DIRECTIVE: AN ALTERNATIVE ENVIRONMENTAL IMPACT ASSESSMENT PROCEDURE AFTER MASSEY? M.S. Thesis
Paul D. McHugh 30 Sep. 1993 100 p
(AD-A275550) Avail: CASI HC A05/MF A02

The similarities and differences between the 'father' of environmental impact assessment (EIA) legislation, the United States' National Environmental Policy Act (NEPA), and one of its important progeny, the 1985 European Community directive requiring member nations to assess the environmental effects of major projects, both private and public, are examined. Both NEPA's and the EC directive's policies and objectives are discussed. The background and procedures of the regulations implementing environmental impact assessment requirements, and opportunities for public participation, are examined. A discussion of the international problems associated with their application is presented. CASI

SYSTEM REQUIREMENTS REVIEW FOR THE HIGH-RESOLUTION OZONE IMAGER (HIROIG) Technical Report
D. L. McKenzie, D. J. Gutierrez, J. H. Hecht, D. J. Mabry, and M. N. Ross 15 Sep. 1993 80 p
(Contract F04701-88-C-0089)
(AD-A275151; TR-93(3231)-2; SMC-TR-93-62) Avail: CASI HC A05/MF A01

The HIROIG System Requirements Review was held on 17 Feb. 1993 at The Aerospace Corporation. The purpose of the review was to demonstrate the way in which the requirements for a spaceborne ozone imaging experiment are derived from the fundamental goal of the program, which is to measure how space-vehicle launches affect the ozone layer of the atmosphere. The review included, towards the end, short presentations on the experiment team's approaches to meeting the program requirements. This report is a compilation of the briefing charts that were presented at the review. DTIC

DEVELOPMENT AND IMPLEMENTATION OF A SCRUB HABITAT COMPENSATION PLAN FOR KENNEDY SPACE CENTER
Paul A. Schmalzer, David R. Breininger, Frederic W. Adrian, Ron Schaub, and Brean W. Duncan Jan. 1994 55 p
(Contract NAS10-11624)
(NASA-TM-109202; NAS 1.15:109202) Avail: CASI HC A04/MF A01

Kennedy Space Center (KSC), located on Merritt Island on the east coast of central Florida, is one of three remaining major populations of the Florida Scrub Jay (Aphelocoma coerulescens coerulescens), listed as threatened by the U.S. Fish and Wildlife Service (USFWS) since 1987. Construction of new facilities by the National Aeronautics and Space Administration (NASA) on KSC over the next five years has the potential to impact up to 193 ac (78.1 ha) of Scrub Jay habitat. Under an early consultation process with the Endangered Species Office of the USFWS, NASA agreed to a compensation plan for loss of Scrub Jay habitat. The compensation plan required NASA to restore or create scrub on KSC at a 2:1 ratio for that lost. The compensation plan emphasized restoration of scrub habitat that is of marginal or declining suitability to Scrub Jays because it has remained unburned. Although prescribed burning has been conducted by the USFWS Merritt Island National Wildlife Refuge (MINWR) for more than ten years, significant areas of scrub remain unburned because they have been excluded from fire management units or because landscape fragmentation and a period of fire suppression allowed scrub to reach heights and diameters that are fire resistant. For such areas, mechanical cutting followed by prescribed burning was recommended for restoration. A second part of the restoration plan is an experimental study of scrub reestablishment (i.e., creation) on abandoned, well drained agricultural sites by planting scrub oaks and other scrub plants. The compensation plan identified 260 ac (105 ha) of scrub restoration in four areas and a 40 ac (16 ha) scrub creation site. Monitoring of restoration sites required under the plan included: establishing permanent vegetation sample transects before treatment and resampling annually for ten years after treatment, and color banding Scrub Jays to determine territories prior to treatment followed by monitoring reproductive success and survival for ten years after treatment. Monitoring scrub creation sites included determining survival of planted material for five years and establishing permanent transects to follow vegetation development for ten years after planting. Scrub Jay monitoring of creation sites is incorporated with that of adjacent restoration sites. Author

CAESIUM-137 IN A BOREAL FOREST ECOSYSTEM: ASPECTS ON THE LONG-TERM BEHAVIOR
R. Bergman, T. Nylen, P. Nelin, and T. Palo Nov. 1993 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(ISSN 0347-2124)
(PB94-137809; FOA-C-40284-4.3) Avail: Issuing Activity (National Technical Information Service (NTIS))

Cycling of radioactive cesium, particularly the isotope Cs-137, is studied in boreal forest biotopes mainly located at the Vindeln experimental forest, 60 km NW of Umea, Sweden. The distribution of radioactive cesium in this forest ecosystem, prior to and in different periods after the Chernobyl accident, reflects the existence of fast changes particularly at an early stage after the deposition, superimposed on slow redistribution over long time periods. The definite causes to this complex dynamic behavior are not yet unambigously established. In the work, the authors use the specific results from local field studies as a basis to describe the general pattern and time dependence of Cs-137 redistribution in a boreal forest. NTIS

CHARACTERIZATION OF AIR EMISSIONS FROM THE SIMULATED OPEN COMBUSTION OF FIBERGLASS MATERIALS Final Report, 1 Jan. - Aug. 1993
C. C. Lutes and J. V. Ryan Dec. 1993 99 p See also PB91-227967 and PB92-115286
(Contract EPA-68-DO-0141)
(PB94-136231; EPA/600/R-93/239) Avail: CASI HC A05/MF A02

The exposure of persons to fiberglass combustion emissions from structural fires, fires at waste landfills, and fires at demolition sites has become an issue of increasing concern. The study identifies and quantifies a broad range of pollutants that are discharged during small-scale, simulated, open combustion of fiberglass and reports these emissions relative to the mass of fiberglass material combusted. Two types of fiberglass materials (representing the boating and building materials industries) were combusted in a controlled outbuilding designed to simulate open burning. Volatile, semivolatile, and particulate-bound organics were collected and analyzed by gas chromatography/mass spectrometry (GC/MS). NTIS

GOME: GLOBAL OZONE MONITORING EXPERIMENT Interim Science Report
T. D. Guyenne, ed. and C. Readings, ed. Sep. 1993 57 p Original contains color illustrations
(ESA-SP-1151; ISBN-92-9092-041-6; ETN-94-95458) Avail: CASI HC A04/MF A01

A review of the scientifc objectives and capabilities of the Global Ozone Monitoring Experiment (GOME), to be carried on the payload of the ERS-2 satellite, to monitor absorption by trace gases in the solar spectrum, is presented. Its actual capabilities are also assessed and some of the calculations underlying the assessment are contained in the annexes. Topics such as calibration and data processing are considered and other experiments (intended to study the chemical composition of the atmosphere) which are planned to fly before the end of the century, are reviewed. This serves to set the GOME into the overall context of atmospheric chemistry studies. ESA

LABORATORY STUDIES OF CHEMICAL AND PHOTOCHEMICAL PROCESSES RELEVANT TO STRATOSPHERIC OZONE Annual Report No. 2, May 1993 - Apr. 1994
Mark S. Zahniser, David D. Nelson, Douglas R. Worsnop, and Charles E. Kolb Apr. 1994 15 p
(Contract NAS5-31847)
(NASA-CR-195779; NAS 1.26:195779; ARI-RR-1072) Avail: CASI HC A03/MF A01

The purpose of this project is to reduce the uncertainty in several key gas-phase kinetic processes which impact our understanding of stratospheric ozone. The main emphasis of this work is on measuring rate coefficients and product channels for reactions of HO(sub x) and NO(sub x) species in the temperature range 200 K to 240 K relevant to the lower stratosphere. Other areas of study have included infrared spectroscopic studies of the HO2 radical, measurements of OH radical reactions with alternative fluorocarbons, and determination of the vapor pressures of nitric acid hydrates under stratospheric conditions. The results of these studies will improve models of stratospheric ozone chemistry and predictions of perturbations due to human influences. In this annual report, we focus on our recent accomplishments in the quantitative spectroscopy of the HO2 radical. This report details the measurements of the broadening coefficients for the v(sub 2) vibrational band. Further measurements of the vapor pressures of nitric acid hydrates relevant to the polar stratospheric cloud formation indicate the importance of metastable crystalline phases of H2SO4, HNO3, and H2O. Large particles produced from these metastable phases may provide a removal mechanism for HNO3 in the polar stratosphere.

GCM STUDIES OF THE INFLUENCE OF VEGETATION ON THE GENERAL CIRCULATION: THE ROLE OF ALBEDO IN MODULATING CLIMATE CHANGE Ph.D. Thesis
Paul Alan Dirmeyer 1992 242 p
Avail: Univ. Microfilms Order No. DA9315631

An atmospheric general circulation model (GCM) coupled to a simple biosphere model is used to examine the role of vegetation change on climate. Various biomes are substituted to simulate degradation of vegetation. It is found that albedo change plays a distinct role in the local decrease of rainfall. Changes in vegetation morphology and physiology do not cause catastrophic decreases in precipitation. Simulations of Amazon deforestation show that the climatic response is very dependent on the amount of change in albedo between rain forest and degraded grass. Precipitation drops as albedo increases. The change in plant physiology decreases evapotranspiration, but moisture convergence increases to offset the drying. This compensation is a result of cloud feedback in this model, and does not occur when cloudiness is prescribed. Experiments with idealized boundary conditions show a similar dependence of rainfall on albedo in cases of tropical deforestation, subtropical desertification, and mid-latitude deforestation. In the tropics, rainfall decreases over land only when reflectivity is increased, even when the rain forest is left intact. The monsoon precipitation of the subtropical experiment fails when savannah is replaced by high-albedo desert. When low-albedo desert is used, the decrease in summer rainfall is small. When mid-latitude forest is replaced by grassland, precipitation patterns shift, but net rainfall remains unchanged. Additional simulations of mid-latitude drought show that low soil moisture leads to moderate spring and summer droughts, but dry soil combined with dormant vegetation produces extremely severe droughts. Soil moisture deficits were more persistent when vegetation did not go dormant. Dissert. Abstr.

OPTICAL MODELING OF VISIBILITY AND VISIBILITY INSTRUMENTATION USING STRATIFIED MIE THEORY Ph.D. Thesis
Ronald Robert Rickards 1992 255 p
Avail: Univ. Microfilms Order No. DA9313523

A new method of matching stratified Mie theory to size-time-composition resolved impactor data is developed and applied to rural data. The new model is free of theoretical systematic errors which exist in the standard approach and also includes the effect of relative humidity in an alternate and improved format. A physical description based on the volume Mie coefficients is emphasized and a corresponding lognormal parameterization scheme is introduced. Both theoretical and experimental results indicate that aerosols in D(sub p) less than 2.5 micron dichotomous sampling protocols are not adequate to predict visible or ultraviolet extinction. Further, to the extent that size shifts occur within the accumulation mode, the experimental results also indicate a limited correlation between those aerosols responsible for visibility reduction and those that extinguish ultraviolet. Hence, in order to better understand and monitor the effect of anthropogenic aerosols on atmospheric visibility and ground level ultraviolet fluxes, we must routinely combine impactor data sets in discrete highly resolved size ranges with stratified Mie theory. In addition, highly instructional computer-generated three dimensional surface plots are presented which convey the global theoretical characteristics of the Mie parameters, including extensions well into the strong absorption region. Dissert. Abstr.

SENSITIVITY AND FEEDBACKS ASSOCIATED WITH VEGETATION-RELATED LAND SURFACE PARAMETERS IN A GENERAL CIRCULATION MODEL Ph.D. Thesis
Brent Melvin Lofgren 1993 214 p
Avail: Univ. Microfilms Order No. DA9316092

A series of general circulation model (GCM) experiments were run to investigate the effects on climate of surface albedo, surface roughness, and field capacity. When decreased surface albedo is prescribed, at low latitudes, precipitation and soil moisture are increased, because of the increased upward motion resulting from additional atmospheric heating. At midlatitudes, the precipitation is insensitive to decreased surface albedo, but soil moisture is decreased. A prescribed decrease in land surface roughness causes a general decrease in evaporation from land and water vapor flux convergence over land, and consequently also in precipitation. In particular, precipitation is reduced along coasts with shoreward winds, where decreased surface roughness results in decreased low-level convergence. In another experiment, land surface albedo was interactive with the GCM climate, using the climate to determine the vegetative cover. When compared to a control case with constant surface albedo over all land, tropical rain forests have increased precipitation and soil moisture. This promotes more growth of vegetation, causing positive feedback within the system. Subtropical deserts have decreased precipitation and soil moisture, again a positive feedback, and there is evidence of a southward shift in the Sahara. Midlatitudes again have little response in precipitation, but have soil moisture responses which imply negative feedback. When surface roughness is interactively predicted, low-latitude forests have increased precipitation, primarily along coasts where there are shoreward winds. This leads to increased vegetation and greater surface roughness, making it a positive feedback. At midlatitudes, particularly in eastern North America, the roughness of the forests causes enhanced Ekman convergence, resulting in increased precipitation. This is also a positive feedback. Interactive field capacity was found to have little or no systematic effect. With its inclusion, neither the pattern of changes in precipitation nor of changes in soil moisture as a fraction of field capacity is clearly correlated to the distribution of initially predicted field capacity. When all three parameters are made interactive simultaneously, the precipitation and soil moisture responses are found to be approximately the sum of the responses to individual parameters, except where more than one parameter produced a large response. Dissert. Abstr.

N94-29901 Miami Univ., Coral Gables, FL.
ANALYSIS AND MODELING OF ENVIRONMENTAL AND ECONOMIC IMPACTS OF THE SOLAR HYDROGEN ENERGY SYSTEM Ph.D. Thesis
Frano Barbir 1992 189 p
Avail: Univ. Microfilms Order No. DA9314507

The solar hydrogen energy system has been designed as a replacement of the present energy system based mainly on fossil fuels. Such a system has been found to be technically feasible. A method for analysis of environmental damage and estimation of associated external costs of fossil fuels has been developed. The analysis indicates that the solar hydrogen energy system might provide the same energy services as fossil fuels, but at lower societal costs, if the costs of environmental damage are taken into account. An analysis of the solar hydrogen energy system and its components has found no insurmountable physical obstacles for its introduction. A model of global energy / environment / economy interactions has been developed using energy circuit language to study the transition to the solar hydrogen energy system. The results of the model simulation indicate that timely transition might benefit the economy and the environment. The solar hydrogen energy system would stop carbon dioxide build up in the atmosphere and might provide energy for human civilization practically forever. Dissert. Abstr.

BRIEF SUMMARY OF ACCOMPLISHMENTS SINCE OUR DOE-SPONSORED RADON PROJECT COMMENCED
1993 16 p

(Contract DE-FG02-88ER-60668)
(DE94-004643; DOE/ER-60668/7) Avail: CASI HC A03/MF A01

We have focused on determining the thermomechanical and kinetic properties that are involved in the interactions of common atmospheric molecules and indoor pollutants. In view of the fact that a large fraction of the progeny ions are thought to be in the singly charged state, we have directed our attention to the evolving chemistry of these species. Emphasis has been placed on acquiring fundamental thermochemical information which will provide a basis for modeling studies. The studies are requisite in obtaining a more complete picture of growth, attachment to aerosols, and ultimately transport to the bioreceptor. DOE

IMPACT OF BIOMASS BURNING ON THE ATMOSPHERE
J. Dignon Mar. 1993 16 p Presented at the North Atlantic Treaty Organization (NATO) Advanced Research Workshop on Ice Core Studies of Global Biogeochemical Cycles, Annecy, France, 26-31 Mar. 1993
(Contract W-7405-eng-48)
(DE94-004333; UCRL-JC-115082; CONF-9303250-1) Avail: CASI HC A03/MF A01

Fire has played an important part in biogeochemical cycling throughout most of the history of our planet. Ice core studies have been very beneficial in paleoclimate studies and constraining the budgets of biogeochemical cycles through the past 160,000 years of the Vostok ice core. Although to date there has been no way of determining cause and effect, concentration of greenhouse gases directly correlates with temperature in ice core analyses. Recent ice core studies on Greenland have shown that significant climate change can be very rapid on the order of a decade. This chapter addresses the coupled evolution of our planet's atmospheric composition and biomass burning. Special attention is paid to the chemical and climatic impacts of biomass burning on the atmosphere throughout the last century, specifically looking at the cycles of carbon, nitrogen, and sulfur. Information from ice core measurements may be useful in understanding the history of fire and its historic affect on the composition of the atmosphere and climate. DOE

THE SUITABILITY OF LOW-COST URBAN AIRSHED MODELING IN THE CHICAGO AREA
M. E. Fernau, W. J. Makofske, and D. W. South 1994 4 p Presented at the 74th American Meteorological Society Annual Meeting, Nashville, TN, 23-28 Jan. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-31-109-eng-38)
(DE94-005114; ANL/DIS/CP-81382; CONF-940115-21) Avail: CASI HC A01

The interesting composition of the utility mix in the Chicago region and the potential for electric vehicle use in that area make it an interesting candidate for emissions sensitivity and scenario studies. However, it is difficult to apply the Urban Airshed Model (UAM) to the Chicago region because of the complex meteorology associated with Lake Michigan. The Lake Michigan Air Directors consortium (LADCO) has developed, at considerable expense, an improved version with nested grids and embedded plumes (UAM-V) for application in the Lake Michigan Ozone Study (LMOS) and for regulatory use. The complexity of the LMOS modeling system makes it costly and time-consuming to implement. In this study, the authors apply UAM-4 in its simple 'PLANR (Practice for Low-cost Application in Nonattainment Regions)' mode to the Chicago region to study various interesting scenarios in a rapid and low-cost manner. The details of the data sets, methods, and results of this study are summarized here. In addition, the authors comment on the usefulness of this type of limited-data study as compared to more complex modeling systems and data inputs. DOE

A COUPLED APPROACH TO SPATIALLY DERIVED PARAMETERS NECESSARY FOR ECOSYSTEM MODELING ON THE NORTH SLOPE OF ALASKA: APPENDIX A
G. W. Petersen, R. L. Day, and J. Pollack Dec. 1993 44 p
(Contract DE-FG02-89ER-60760)
(DE94-005853; DOE/ER-60760/5-App-A) Avail: CASI HC A03/MF A01

This study concerned an investigation of ecosystem dynamics in several small study sites in the North Slope region of Alaska. The scope of the proposed research is to quantitatively determine spatial interrelationships between landform geometry within these study areas and such ecologically important factors as vegetation type, depth-to-permafrost, hydraulic conductivity and incoming solar radiation. Extrapolation techniques developed and terrain-related data generated as a result of this research will augment R4D Phase 2 goals which relate to running the General Arctic Simulac (GAS) model (and associated ecosystem models) at different locations on the North Slope. In particular, Penn State has contributed significantly to extrapolation efforts by developing techniques which can be used to initialize conditions for model input either through direct measurement (e.g., slope and aspect) and GIS-based simulation models (e.g., drainage basin characterization). As stated in the R4D Phase 2 Research Plan, the long-term objectives of this program are: (1) to determine effects and to develop models based on ecosystem disturbances commonly created by energy development so that appropriate, cost-effective measures can be utilized to minimize deleterious disturbances; and (2) to extend the results to other arctic and alpine areas which are important because of likely impact from energy development. It is this second long-term objective which relates most directly to Penn State's work. DOE

N94-30047# SRI International Corp., Menlo Park, CA.
NOVEL MASS SPECTROMETRIC INSTRUMENT FOR GASEOUS AND PARTICULATE CHARACTERIZATION AND MONITORING
M. J. Coggiola Jul. 1993 17 p
(Contract DE-AC21-92MC-29116)
(DE94-005896; DOE/MC-29116/3575) Avail: CASI HC A03/MF A01

A mass spectrometric (MS) instrument is being developed for real-time (less than 1 min) analysis of gaseous and particulate pollutants from DOE waste cleanup activities. The pollutants will include volatile organic compounds, PAHs, heavy metals, and transuranics. Design has been completed for the sampler and its vacuum interface with ion trap detectors and fabrication started. Design, fabrication, and testing of pyrolysis filament for particulate analysis is under way. DOE

PCCM2: A GCM ADAPTED FOR SCALABLE PARALLEL COMPUTERS

J. Drake, B. D. Semeraro, P. Worley, I. Foster, J. Michalakes, B. Toonen, J. J. Hack, and D. L. Williamson 1994 8 p Presented at the 5th Annual Symposium on Global Change Studies, Nashville, TN, 24-28 Jan. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract W-31-109-eng-38)

(DE94-005113; ANL/MCS/CP-81098; CONF-940131-3) Avail: Issuing Activity (Department of Energy (DOE))

The Computer Hardware, Advanced Mathematics, and Model Physics (CHAMMP) program seeks to provide climate researchers with an advanced modeling capability for the study of global change issues. One of the more ambitious projects being undertaken in the CHAMMP program is the development of PCCM2, an adaptation of the Community Climate Model (CCM2) for scalable parallel computers. PCCM2 uses a message-passing, domain-decomposition approach, in which each processor is allocated responsibility for computation on one part of the computational grid, and messages are generated to communicate data between processors. Much of the research effort associated with development of a parallel code of this sort is concerned with identifying efficient decomposition and communication strategies. In PCCM2, this task is complicated by the need to support both semi-Lagrangian transport and spectral transport. Load balancing and parallel I/O techniques are also required. In this paper, the authors review the various parallel algorithms used in PCCM2 and the work done to arrive at a validated model. DOE

RADIATIVE FLUX CALCULATIONS AT UV AND VISIBLE WAVELENGTHS

A. S. Grossman, K. E. Grant, and D. J. Wuebbles Oct. 1993 7 p

(Contract W-7405-eng-48)

(DE94-004278; UCRL-ID-115336) Avail: CASI HC A02/MF A01

A radiative transfer model to calculate the short wavelength fluxes at altitudes between 0 and 80 km was developed at LLNL. The wavelength range extends from 175-735 nm. This spectral range covers the UV-B wavelength region, 250-350 nm, with sufficient resolution to allow comparison of UV-B measurements with theoretical predictions. Validation studies for the model were made for both UV-B ground radiation calculations and tropospheric solar radiative forcing calculations for various ozone distributions. These studies indicate that the model produces results which agree well with respect to existing UV calculations from other published models. DOE

THE CARBON CYCLE REVISITED

Bert Bolin and Inez Fung *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 151-164 (For primary document see N94-30616 08-45)

Avail: CASI HC A03/MF A04

Discussions during the Global Change Institute indicated a need to present, in some detail and as accurately as possible, our present knowledge about the carbon cycle, the uncertainties in this knowledge, and the reasons for these uncertainties. We discuss basic issues of internal consistency within the carbon cycle, and end by summarizing the key unknowns.

OCEAN-ATMOSPHERIC LINKAGES

Stephen R. Rintoul *In* University Corp. for Atmospheric Research, Modeling

the Earth System, Volume 3 1992 p 165-180 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

This chapter focuses on the role of the ocean in the global carbon cycle on the time scale of decades to centuries. The input rate of CO2 to the atmosphere due to fossil fuel burning and deforestation has continued to increase over the last century. To balance the global carbon budget, a sink is required whose magnitude is changing on similar time scales. We have sought to identify aspects of the ocean system that are capable of responding on decadal time scales, to examine our present ability to model such changes, and to pinpoint ways in which this ability could be improved. Many other important aspects of the ocean's role in global change are not addressed, including the importance of oceanic heat transport and thermal inertia to the climate system, biogeochemical cycling of elements other than carbon, and the importance of the ocean as a source or sink of trace gases. LINKAGES BETWEEN TERRESTRIAL ECOSYSTEMS AND THE ATMOSPHERE
Francis Bretherton (Wisconsin Univ., Madison.), Robert E. Dickinson (Arizona Univ., Tucson.), Inez Fung, Berrien Moore, III, Michael Prather, Steven W. Running, and Holm Tiessen *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 181-196 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

The primary research issue in understanding the role of terrestrial ecosystems in global change is analyzing the coupling between processes with vastly differing rates of change, from photosynthesis to community change. Representing this coupling in models is the central challenge to modeling the terrestrial biosphere as part of the earth system. Terrestrial ecosystems participate in climate and in the biogeochemical cycles on several temporal scales. Some of the carbon fixed by photosynthesis is incorporated into plant tissue and is delayed from returning to the atmosphere until it is oxidized by decomposition or fire. This slower (i.e., days to months) carbon loop through the terrestrial component of the carbon cycle, which is matched by cycles of nutrients required by plants and decomposers, affects the increasing trend in atmospheric CO2 concentration and imposes a seasonal cycle on that trend. Moreover, this cycle includes key controls over biogenic trace gas production. The structure of terrestrial ecosystems, which responds on even longer time scales (annual to century), is the integrated response to the biogeochemical and environmental constraints that develop over the intermediate time scale. The loop is closed back to the climate system since it is the structure of ecosystems, including species composition, that sets the terrestrial boundary condition in the climate system through modification of surface roughness, albedo, and, to a great extent, latent heat exchange. These separate temporal scales contain explicit feedback loops which may modify ecosystem dynamics and linkages between ecosystems and the atmosphere. The long-term change in climate, resulting from increased atmospheric concentrations of greenhouse gases (e.g., CO2, CH4, and nitrous oxide (N2O)) will further modify the global environment and potentially induce further ecosystem change. Modeling these interactions requires coupling successional models to biogeochemical models to physiological models that describe the exchange of water, energy, and biogenic trace gases between the vegetation and the atmosphere at fine time scales. There does not appear to be any obvious way to allow direct reciprocal coupling of atmospheric general circulation models (GCM's), which inherently run with fine time steps, to ecosystem or successional models, which have coarse temporal resolution, without the interposition of physiological canopy models. This is equally true for biogeochemical models of the exchange of carbon dioxide and trace gases. This coupling across time scales is nontrivial and sets the focus for the modeling strategy.

FOUR SIMPLE OCEAN CARBON MODELS
Berrien Moore, III *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 197-223 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

This paper briefly reviews the key processes that determine oceanic CO2 uptake and sets this description within the context of four simple ocean carbon models. These models capture, in varying degrees, these key processes and establish a clear foundation for more realistic models that incorporate more directly the underlying physics and biology of the ocean rather than relying on simple parametric schemes. The purpose of this paper is more pedagogical than purely scientific. The problems encountered by current attempts to understand the global carbon cycle not only require our efforts but set a demand for a new generation of scientist, and it is hoped that this paper and the text in which it appears will help in this development. A TOY MODEL OF SEA ICE GROWTH
Alan S. Thorndike *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 225-238 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

My purpose here is to present a simplified treatment of the growth of sea ice. By ignoring many details, it is possible to obtain several results that help to clarify the ways in which the sea ice cover will respond to climate change. Three models are discussed. The first deals with the growth of sea ice during the cold season. The second describes the cycle of growth and melting for perennial ice. The third model extends the second to account for the possibility that the ice melts away entirely in the summer. In each case, the objective is to understand what physical processes are most important, what ice properties determine the ice behavior, and to which climate variables the system is most sensitive.

A BOTTOM-UP EVOLUTION OF TERRESTRIAL ECOSYSTEM MODELING THEORY, AND IDEAS TOWARD GLOBAL VEGETATION MODELING
Steven W. Running *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 263-280 (For primary document see N94-30616 08-45)
(Contract NAS5-30920; NAGw-252; NSF BSR-88-17965)
Avail: CASI HC A03/MF A04

A primary purpose of this review is to convey lessons learned in the development of a forest ecosystem modeling approach, from it origins in 1973 as a single-tree water balance model to the current regional applications. The second intent is to use this accumulated experience to offer ideas of how terrestrial ecosystem modeling can be taken to the global scale: earth systems modeling. A logic is suggested where mechanistic ecosystem models are not themselves operated globally, but rather are used to 'calibrate' much simplified models, primarily driven by remote sensing, that could be implemented in a semiautomated way globally, and in principle could interface with atmospheric general circulation models (GCM's).

DEVELOPMENT OF SIMPLIFIED ECOSYSTEM MODELS FOR APPLICATIONS IN EARTH SYSTEM STUDIES: THE CENTURY EXPERIENCE

William J. Parton, Dennis S. Ojima, David S. Schimel, and Timothy G. F. Kittel *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 281-302 (For primary document see N94-30616 08-45)

Avail: CASI HC A03/MF A04

During the past decade, a growing need to conduct regional assessments of long-term trends of ecosystem behavior and the technology to meet this need have converged. The Century model is the product of research efforts initially intended to develop a general model of plant-soil ecosystem dynamics for the North American central grasslands. This model is now being used to simulate plant production, nutrient cycling, and soil organic matter dynamics for grassland, crop, forest, and shrub ecosystems in various regions of the world, including temperate and tropical ecosystems. This paper will focus on the philosophical approach used to develop the structure of Century. The steps included were model simplification, parameterization, and testing. In addition, the importance of acquiring regional data bases for model testing and the present regional application of Century in the Great Plains, which focus on regional ecosystem dynamics and the effect of altering environmental conditions, are discussed. CARBON CYCLING IN HIGH-LATITUDE ECOSYSTEMS

Alan Townsend, Stephen Frolking, and Elizabeth Holland *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 315-326 (For primary document see N94-30616 08-45)

Avail: CASI HC A03/MF A04

The carbon-rich soils and peatlands of high-latitude ecosystems could substantially influence atmospheric concentrations of CO2 and CH4 in a changing climate. Currently, cold, often waterlogged conditions retard decomposition, and release of carbon back to the atmosphere may be further slowed by physical protection of organic matter in permafrost. As a result, many northern ecosystems accumulate carbon over time (Billings et al., 1982; Poole and Miller, 1982), and although such rates of accumulation are low, thousands of years of development have left Arctic ecosystems with an extremely high soil carbon content; Schlesinger's (1984) average value of 20.4 kg C/m(sup 2) leads to a global estimate of 163 x 10(exp 15) g C. All GCM simulations of a doubled CO2 climate predict the greatest warming to occur in the polar regions (Dickinson, 1986; Mitchell, 1989). Given the extensive northern carbon pools and the strong sensitivity of decomposition processes to temperature, even a slight warming of the soil could dramatically alter the carbon balance of Arctic ecosystems. If warming accelerates rates of decomposition more than rates of primary production, a sizeable additional accumulation of CO2 in the atmosphere could occur. Furthermore, CH4 produced in anaerobic soils and peatlands of the Arctic already composes a good percentage of the global efflux (Cicerone and Oremlund, 1988); if northern soils become warmer and wetter as a whole, CH4 emissions could dramatically rise. A robust understanding of the primary controls of carbon fluxes in Arctic ecosystems is critical. As a framework for a systematic examination of these controls, we discussed a conceptual model of regional-scale Arctic carbon turnover, including CH4 production, and based upon the Century soil organic matter model. CRYOSPHERE AND CLIMATE

William D. Hibler, III and Alan S. Thorndike *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 327-333 (For primary document see N94-30616 08-45)

Avail: CASI HC A02/MF A04

This chapter will discuss two main issues related to the cryosphere and climate. One is the effect of sea ice and salinity gradients on ocean circulation, and in particular the possible role of sea ice transport on the ocean conveyer belt. The other is the effect of the cryosphere on climate, and in particular in high-latitude warming under increased CO2. In understanding the role of the cryosphere in both cases, it is useful to elucidate two types of toy sea ice models. Neither of these represents reality, but both are useful for illustrating the archetypal features of sea ice that control much of its large-scale behavior. The first model is a simple slab thermodynamic sea ice model as presented by Thorndike. In this model there are no dynamical effects and the thickness of ice is determined by surface heat budget and oceanic heat flux considerations, with the thickness of the ice critically affecting the effective conductivity whereby heat is transferred from the bottom ice boundary to the upper ice boundary. In this model all of the sea ice characteristics are controlled by the vertical heat fluxes from the atmosphere and ocean into the ice. The thickness is controlled by the ice's becoming an effective insulator as it thickens, thus reducing conductive heat loss to the atmosphere. A second model emphasizes the effects of dynamics. It considers the ice pack to be a collection of floes moving in response to synoptic wind fields and ocean currents. These motions create semipermanent leads (open areas) over which ice can grow rapidly. Derived from text

METHODS OF TESTING PARAMETERIZATIONS: VERTICAL OCEAN MIXING

Eli Tziperman *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 335-358 (For primary document see N94-30616 08-45)

Avail: CASI HC A03/MF A04

The ocean's velocity field is characterized by an exceptional variety of scales. While the small-scale oceanic turbulence responsible for the vertical mixing in the ocean is of scales a few centimeters and smaller, the oceanic general circulation is characterized by horizontal scales of thousands of kilometers. In oceanic general circulation models that are typically run today, the vertical structure of the ocean is represented by a few tens of discrete grid points. Such models cannot explicitly model the small-scale mixing processes, and must, therefore, find ways to parameterize them in terms of the larger-scale fields. Finding a parameterization that is both reliable and plausible to use in ocean models is not a simple task. Vertical mixing in the ocean is the combined result of many complex processes, and, in fact, mixing is one of the less known and less understood aspects of the oceanic circulation. In present models of the oceanic circulation, the many complex processes responsible for vertical mixing are often parameterized in an oversimplified manner. Yet, finding an adequate parameterization of vertical ocean mixing is crucial to the successful application of ocean models to climate studies. The results of general circulation models for quantities that are of particular interest to climate studies, such as the meridional heat flux carried by the ocean, are quite sensitive to the strength of the vertical mixing. We try to examine the difficulties in choosing an appropriate vertical mixing parameterization, and the methods that are available for validating different parameterizations by comparing model results to oceanographic data. First, some of the physical processes responsible for vertically mixing the ocean are briefly mentioned, and some possible approaches to the parameterization of these processes in oceanographic general circulation models are described in the following section. We then discuss the role of the vertical mixing in the physics of the large-scale ocean circulation, and examine methods of validating mixing parameterizations using large-scale ocean models. THE CHALLENGE OF IDENTIFYING GREENHOUSE GAS-INDUCED CLIMATIC CHANGE

Michael C. MacCracken *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 359-376 (For primary

document see N94-30616 08-45)
(Contract W-7405-eng-48)
Avail: CASI HC A03/MF A04

Meeting the challenge of identifying greenhouse gas-induced climatic change involves three steps. First, observations of critical variables must be assembled, evaluated, and analyzed to determine that there has been a statistically significant change. Second, reliable theoretical (model) calculations must be conducted to provide a definitive set of changes for which to search. Third, a quantitative and statistically significant association must be made between the projected and observed changes to exclude the possibility that the changes are due to natural variability or other factors. This paper provides a qualitative overview of scientific progress in successfully fulfilling these three steps. Derived from text

MODELS OF ATMOSPHERE-ECOSYSTEM-HYDROLOGY INTERACTIONS: APPROACHES AND TESTING
David S. Schimel *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 405-421 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

Interactions among the atmosphere, terrestrial ecosystems, and the hydrological cycle have been the subject of investigation for many years, although most of the research has had a regional focus. The topic is broad, including the effects of climate and hydrology on vegetation, the effects of vegetation on hydrology, the effects of the hydrological cycle on the atmosphere, and interactions of the cycles via material flux such as solutes and trace gases. The intent of this paper is to identify areas of critical uncertainty, discuss modeling approaches to resolving those problems, and then propose techniques for testing. I consider several interactions specifically to illustrate the range of problems. These areas are as follows: (1) cloud parameterizations and the land surface, (2) soil moisture, and (3) the terrestrial carbon cycle. Author (revised)

EVALUATING MODELS OF CLIMATE AND FOREST VEGETATION
James S. Clark *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 423-440 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

Understanding how the biosphere may respond to increasing trace gas concentrations in the atmosphere requires models that contain vegetation responses to regional climate. Most of the processes ecologists study in forests, including trophic interactions, nutrient cycling, and disturbance regimes, and vital components of the world economy, such as forest products and agriculture, will be influenced in potentially unexpected ways by changing climate. These vegetation changes affect climate in the following ways: changing C, N, and S pools; trace gases; albedo; and water balance. The complexity of the indirect interactions among variables that depend on climate, together with the range of different space/time scales that best describe these processes, make the problems of modeling and prediction enormously difficult. These problems of predicting vegetation response to climate warming and potential ways of testing model predictions are the subjects of this chapter. Author (revised)

COMPREHENSIVE SYSTEM MODELS: STRATEGIES FOR EVALUATION
Christopher Field, John E. Kutzbach, V. Ramanathan, and Michael C. MacCracken *In* University Corp. for Atmospheric Research, Modeling the Earth System, Volume 3 1992 p 441-462 (For primary document see N94-30616 08-45)
Avail: CASI HC A03/MF A04

The task of evaluating comprehensive earth system models is vast involving validations of every model component at every scale of organization, as well as tests of all the individual linkages. Even the most detailed evaluation of each of the component processes and the individual links among them should not, however, engender confidence in the performance of the whole. The integrated earth system is so rich with complex feedback loops, often involving components of the atmosphere, oceans, biosphere, and cryosphere, that it is certain to exhibit emergent properties very difficult to predict from the perspective of a narrow focus on any individual component of the system. Therefore, a substantial share of the task of evaluating comprehensive earth system models must reside at the level of whole system evaluations. Since complete, integrated atmosphere/ ocean/ biosphere/ hydrology models are not yet operational, questions of evaluation must be addressed at the level of the kinds of earth system processes that the models should be competent to simulate, rather than at the level of specific performance criteria. Here, we have tried to identify examples of earth system processes that are difficult to simulate with existing models and that involve a rich enough suite of feedbacks that they are unlikely to be satisfactorily described by highly simplified or toy models. Our purpose is not to specify a checklist of evaluation criteria but to introduce characteristics of the earth system that may present useful opportunities for model testing and, of course, improvement. ELECTRIC POWER LINES: QUESTIONS AND ANSWERS ON RESEARCH INTO HEALTH EFFECTS
Nov. 1993 48 p
(DE94-005637; DOE/BP-2081) Avail: CASI HC A03/MF A01

Most people know that electric power lines, like the wiring in our homes, can cause serious electric shocks if we're not careful. Many people also want to know whether the electric and magnetic fields (EMF) produced by power lines and other electrical devices cause health effects. The purpose of this pamphlet is to answer some common questions that the Bonneville Power Administration (BPA) receives about the possible effects of power

lines on health. (BPA is the Pacific Northwest's Federal electric power marketing agency.) First, some basic electrical terms are defined, and electric and magnetic fields are described. Next, answers are given to several questions about recent scientific studies. We then describe how BPA is addressing public concerns raised by these studies. Some important information about electrical safety follows. The last section tells you how to obtain more detailed information about the health and safety issues summarized in this pamphlet. DOE

FIELD GUIDE TO CRETACEOUS-TERTIARY BOUNDARY SECTIONS IN NORTHEASTERN MEXICO
Gerta Keller (Princeton Univ., NJ.), Wolfgang Stinnesbeck (Universidad Nacional Autonoma de Mexico, Mexico City.), Thierry Adatte (Neuchatel Univ., Switzerland.), Norman MacLeod (Princeton Univ., NJ.), and Donald R. Lowe (Stanford Univ., CA.) 1994 122 p Conference on New Developments Regarding the KT Event and Other Catastrophes in Earth History, held in Houston, TX, 5-8 Feb. 1994 Prepared in cooperation with Houston Univ., Clear Lake, TX
(Contract NASw-4574)
(NASA-CR-195719; NAS 1.26:195719; LPI-Contrib-827) Avail: CASI HC A06/MF A02

This guide was prepared for the field trip to the KT elastic sequence of northeastern Mexico, 5-8 February 1994, in conjunction with the Conference on New Developments Regarding the KT Event and Other Catastrophes in Earth History, held in Houston, Texas. The four-day excursion offers an invaluable opportunity to visit three key outcrops: Arroyo El Mimbral, La Lajilla, and El Pinon. These and other outcrops of this sequence have

recently been interpreted as tsunami deposits produced by the meteorite impact event that produced the 200 to 300-km Chicxulub basin in Yucatan, and distributed ejecta around the world approximately 65 m.y. ago that today is recorded as a thin clay layer found at the K/T boundary. The impact tsunami interpretation for these rocks has not gone unchallenged, and others examining the outcrops arrive at quite different conclusions: not tsunami deposits but turbidites; not KT at all but 'upper Cretaceous.' Indeed, it is in hopes of resolving this debate through field discussion, outcrop evaluation, and sampling that led the organizers of the conference to sanction this field trip. This field guide provides participants with background information on the KT clastic sequence outcrops and is divided into two sections. The first section provides regional and logistical context for the outcrops and a description of the clastic sequence. The second section presents three representative interpretations of the outcrops by their advocates. There is clearly no way that these models can be reconciled and so two, if not all three, must be fundamentally wrong. Readers of this guide should keep in mind that many basic outcrop observations that these models are based upon remain unresolved. While great measures were taken to ensure that the information in the description section was as objective as possible, many observations are rooted in interpretations and the emphasis placed on certain observations depends to some degree upon the perspective of the author. DISLOCATION THEORY OF MELTING FOR IRON, REVISITED
J. P. Poirier (Institut de Physique du Globe, Paris, France.) and T. J. Shankland 1993 5 p Presented at the 14th International Conference of the International Association for the Advancement of High Pressure Science and Technology, Colorado Springs, CO, 27 Jun. - 2 Jul. 1993
(Contract W-7405-eng-36)
(DE94-002715; LA-UR-93-3658; CONF-930676-63) Avail: CASI HC A01/MF A01

Melting point T(sub m) of iron at conditions of the Earth's inner core boundary (ICB) has been calculated from dislocation theory of melting in metals. Monte Carlo calculations were used to estimate uncertainties introduced by uncertainty in the geophysical parameters that are used in the calculations. These calculations take into account the effects of pressure at ICB conditions and of possible freezing point depression resulting from dilution of pure iron in the outer core. With this approach T(sub m) of pure (var epsilon)-Fe at a pressure of 330 GPa and without freezing point depression is 6160 (+/-) 250 K; for a 1000 K freezing point depression it is 6110 K. T(sub m) of pure (gamma)-Fe is 6060 K, a value that is not significantly different. A possible (alpha)' phase would melt at 5600 K. These values agree with calculated shock wave determinations of T(sub m). Although calculated T(sub m) of the pure phase is little affected by assumptions about the extent of freezing point depression, the estimated temperature of the inner core boundary is lower by the freezing point depression, perhaps 500 - 1000 K less than T(sub m) of a pure phase. SUMMARIES OF FY 1993 GEOSCIENCES RESEARCH
Dec. 1993 155 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE94-004710; DOE/ER-0597P) Avail: CASI HC A08

The Department of Energy supports research in the geosciences in order to provide a sound foundation of fundamental knowledge in those areas of the geosciences that are germane to the DOE's many missions. The Geosciences Research Program is supported by the Office of Energy Research. The participants in this program include DOE laboratories, academic institutions, and other governmental agencies. These activities are formalized by a contract or grant between the DOE and the organization performing the work, providing funds for salaries, equipment, research materials, and overhead. The summaries in this document, prepared by the investigators, describe the scope of the individual programs. The Geosciences Research Program includes research in geophysics, geochemistry, resource evaluation, solar-terrestrial interactions, and their subdivisions including earth dynamics, properties of earth materials, rock mechanics, underground imaging, rock-fluid interactions, continental scientific drilling, geochemical transport, solar-atmospheric physics, and modeling, with emphasis on the interdisciplinary areas. ELECTRON BEAMS AT GEOSYNCHRONOUS ORBIT M.S. Thesis
Raymond C. Gaw Sep. 1993 102 p
(AD-A275471) Avail: CASI HC A06/MF A02

This thesis surveys electron and ion measurements collected by the geosynchronous satellite 1989-046. In particular, this survey focuses on a phenomenon known as electron beams, which are attributed to the sudden acceleration of electrons along the earth's magnetic field lines. Observations over a twelve day period reveal electron beam occurrences during the first few minutes of hot plasma injection associated with a magnetospheric substorm. Analysis of distribution functions show these beams have a characteristic peak. These distributions can be approximately fitted as Maxwellians, providing a means of characterizing the temperature, density, and potential drop associated with the beam. Plots of the differential flux also show a general diffusion of the beam into neighboring pitch angles. Theories on the source of the acceleration and diffusion are presented. DTIC

UPDATED DEEP-TOW ACOUSTICS/GEOPHYSICS SYSTEM COMPRESSIONAL VELOCITY DATABASE Final Report
Mary M. Rowe and Joseph F. Gettrust 12 Jan. 1994 21 p
(AD-A275477; NRL/MR/7432-93-7081) Avail: CASI HC A03/MF A01

This memorandum report describes the deep-tow acoustics/geophysics system (DTAGS) compressional velocity database, a compilation of compressional velocity-layer thickness functions derived from DTAGS deep-tow multichannel seismic data. Geologic environments represented by the velocity functions included in this database include thick turbidite deposits, thick sediment basin deposits, sediment containing methane hydrate, and thin sediments overlying young basement. Horizontal sampling frequency (distance between velocity profiles) of the database ranges from 45 to 230 m. Vertical sampling frequency (layer thickness) ranges from 5 to 300 m. These compressional velocity-layer thickness profiles were determined from DTAGS multichannel seismic data using standard semblance velocity analysis procedures. DTIC

A FRACTAL ANALYSIS OF NEAR-FIELD ATMOSPHERIC CONCENTRATION DATA Final Report, 1 Nov. 1992 - 31 Oct. 1993
Franklin A. Gifford 25 Nov. 1993 48 p
(Contract DAAH04-93-C-0002)
(AD-A275460; ARO-29192.1-GS-S) Avail: CASI HC A03/MF A01

A previous study showed that regional and large scale atmospheric motions have Hurst exponents on the order of .4 to .5. The Hurst exponent, H, equals 2-D, where D is the fractal dimension, for a time series. These numbers characterize the degree of irregularity of the time-series. Hurst exponents were calculated for a large number of concentration-time series from several sources, whose sampling times ranged from 6 seconds to 1 hour. Hurst exponents for these data ranged from about .2 to .4. Such values indicate that the small-scale, near-field turbulent eddies differ qualitively from the larger-scale motions, for which H approaches the value .5, the value for Brownian motion. Since models in effect assume the value H = .5 in turbulence parameterizations, these results suggest that smaller, realistic H-values, appropriate to planetary boundary layer turbulence, should be used to parameterize turbulence. A PROGRAM FOR RAPID COMPUTATION OF MULTIOFFSET VERTICAL SEISMIC PROFILE SYNTHETIC SEISMOGRAMS FOR LAYERED MEDIA Final Report
Dennis Lindwall and Subhashis Mallick 4 Jan. 1994 43 p
(NR Proj. 032-02)
(AD-A275464; NRL/MR/7432-93-7022) Avail: CASI HC A03/MF A01

PNSEB is a set of FORTRAN programs for calculating the response of a layered elastic medium using the reflectivity method as described in Mallick and Frazer (Practical Aspects of Reflectivity Modeling, Geophysics 52, 1355-1364, 1987; Rapid Computation of Multi-offset VSP Synthetic Seismograms for Layered Media, Geophysics 53, 479-491, 1988). PNSEB consists of two basic modules, each of which consists of more than one major option. The first module, PNSN, calculates the earth's response (Green's function) in frequency-wavenumber (omega-p) space. Using the proper option, the program can calculate the response at very small or

very large offsets. No lateral variability or anisotropy are allowed, but the full response including interface waves is calculated. The second module, PNSYN, in its main form converts the output from PNSN to time-distance (t-x) space, which can then be plotted by the VSPLT module or by other plotting packages. The program has been written and optimized for vector computers, such as a Cray or Convex, but also runs well on scalar computers such as Sun workstations. DTIC

BROAD GEOACOUSTIC ASSESSMENT OF SOME REGIONAL AREAS Final Report
James K. Fulford 17 Dec. 1993 26 p
(NR Proj. H12-92)
(AD-A275504; NRL/MR/7175-93-7055) Avail: CASI HC A03/MF A01

A broad geoacoustic assessment of three regional shallow-water areas has been made. The geoacoustic properties within each region are mapped into three geoacoustic models representing low (sand-sift-clay), moderate (clayey-sift), and high (silty-clay) bottom loss. Representative extreme sound speed profiles are used to generate a cone of launch angles where the loss is less than a specified amount per bounce. In general, only regions of low loss have good propagation characteristics for each extreme of sound speed. DTIC

THE KLEIN-FOCK EQUATION, MINIMAL SURFACES AND GRAVITATIONAL FIELDS
F. I. Fedorov and N. S. Shavokhina 1992 12 p
(DE94-606340; JINR-E-2-92-377) Avail: CASI HC A03/MF A01 (US Sales Only)

A nonlinear scalar field of the Born-Infeld type is considered whose linear analog is the scalar field obeying the Klein-Fock equation. It is shown that if the initial scalar field is massless, a nonlinear field of the Born-Infeld type corresponding to it is described by the equations of minimal surfaces in pseudo-Euclidean spaces with the coordinates ct, x, and b phi. The coordinate phi may have both space-like and time-like nature. If the initial field is massive, the corresponding field of the Born-Infeld type is described by the equations of minimal surfaces in curved spaces with the same coordinates ct, x, and b phi. Massive fields of the Born-Infeld type are extended sources of the gravitational fields. DOE

FAR ULTRAVIOLET IMAGES OF THE NIGHTTIME IONOSPHERE M.S. Thesis
Thomas P. Hekman 23 Sep. 1993 66 p
(AD-A275083) Avail: CASI HC A04/MF A01

The Naval Research Laboratory's Far Ultraviolet Cameras Experiment is part of an ongoing project to develop a means for real time space based monitoring of the upper atmosphere. A method by which useable data can be extracted from the images obtained from the cameras is developed. The required output is an intensity profile of the light in the band of the camera as a function of observation zenith angle. From this data future analysis can be done to determine the spatial distribution and density of the upper atmosphere. The long term application of this project is to develop a method for using space based imaging of the ionosphere to provide real time radio frequency propagation analysis. DTIC

SPACE-TIME STRUCTURE OF THE MORNING AURORA INFERRED FROM COINCIDENT DMSP-F6, -F8, AND SONDRESTROM INCOHERENT SCATTER RADAR OBSERVATIONS
J. Watermann, O. DeLaBeaujardiere, and H. E. Spence 1 Oct. 1993 16 p
(Contract F04701-88-C-0089)
(AD-A275442; TR-92(2940)-4; SMC-TR-93-63) Avail: CASI HC A03/MF A01

On rare occasions, observations from the DMSP-F6 and -F8 spacecraft and the Sondrestrom incoherent scatter radar coincide in space. Such coincidence offers a unique opportunity to study temporal vs spatial variations on a small scale. We discuss data from one of those occasions, with observations made in the dawn sector in the presence of moderate auroral precipitation during a magnetically quiet period. The DMSP satellites measured vertical electron and ion flux and cross-track plasma drift while the radar measured the ionospheric electron density distribution and line-of-sight plasma velocities. We combine these data sets to construct a two-dimensional map of a possible auroral pattern above Sondrestrom. It is characterized by the following properties. No difference is seen between the gross precipitation patterns measured along the DMSP-F6 and -F8 trajectories (separated by 32 km in magnetic east-west direction and some 4 s in travel time in magnetic north-south direction), except that they are not exactly aligned with the L shells. However, F6 and F8 observed minor differences in the small-scale structures. More significant differences are found between small-scale features in the DMSP precipitation measurements and in radar observations of the E-region plasma density distribution. These measurements are separated by 74 km, equivalent to 2.4 deg, in magnetic longitude, and 0-40 s in time along the spacecraft trajectories (varying with magnetic latitude). Large-scale magnetospheric-ionospheric surfaces such as plasma flow reversal, poleward boundary of the keV ion and electron precipitation, and poleward boundary of E-region ionization, coincide. DTIC

TOWARD A MOLECULAR SCALE UNDERSTANDING OF FROST HEAVING, PHASE 1 Final Report, 15 Apr. 1990 - 30 Sep. 1993
John H. Cushman 13 Dec. 1993 15 p
(Contract DAAL03-90-G-0074)
(AD-A275446; ARO-27316.7-GS) Avail: CASI HC A03/MF A01

A fundamental understanding of the physical and chemical basis for frost heaving is of utmost importance for improving the design of structures for use in cold regions. The research reported here represents a multidisciplinary effort to develop a molecular-scale understanding of this cold region phenomena. Propagation of the molecular-scale information to a field scale is also important and the scale-up problem has also been addressed. A multiphase, multicomponent hybrid theory of mixtures approach was used to scale up information. Equilibrium and nonequilibrium statistical mechanical tools were developed and employed to examine nonlocal diffusion and dispersion. Phase transitions were studied with MC and MD methods. New techniques were developed to compute the chemical potential of the vicinal phase. Interfacial tension was studied using GCEMC. Anomalous diffusion in monolayer films was analyzed via MD, scaling arguments and fractal Brown motion. DTIC

THE EFFECTS OF MAGNETIC STORM PHASES ON F-LAYER IRREGULARITIES FROM AURORAL TO EQUATORIAL LATITUDES Quarterly Report, 1 Oct. - 31 Dec. 1993
Jules Aarons and Michael Mendillo 31 Dec. 1993 4 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1754)
(AD-A275203) Avail: CASI HC A01

During this quarter, an extensive review of the literature on middle latitude irregularities was started. In earlier reports we have noted the levels of irregularities at latitudes above the equatorial anomaly region (within 15 deg of the magnetic equator) thru our analysis of a few examples of raw data from Osan, Korea. We then began to reduce and analyze

data from Puerto Rico and Hawaii using 136 MHz scintillation data taken during both high and low solar flux years. At the levels that can be noted (peak to peak excursions of 15-20 dB) there is considerable activity.

SHARC, A MODEL FOR CALCULATING ATMOSPHERIC AND INFRARED RADIATION UNDER NON-EQUILIBRIUM CONDITIONS
R. L. Sundberg, J. W. Duff, J. H. Gruninger, L. S. Bernstein, and R. D. Sharma 24 Jan. 1994 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A275207; PL-TR-94-2010) Avail: CASI HC A03

A new computer model, SHARC, has been developed by the Air Force for calculating high-altitude atmospheric IR radiance and transmittance spectra with a resolution of better than 1/cm. Comprehensive coverage of the 2 to 40 microns (250/cm to 5,000/cm) wavelength region is provided for arbitrary lines of sight in the 50-300 km altitude regime. SHARC accounts for the deviation from local thermodynamic equilibrium (LTE) in vibrational state populations by explicitly modeling the detailed production, loss, and energy transfer process among the important molecular vibrational states. The calculated vibrational populations are found to be similar to those obtained from other non-LTE codes. The radiation transport algorithm is based on a single-line equivalent width approximation along with a statistical correction for line overlap. This approach is reasonably accurate for most applications and is roughly two orders of magnitude faster than the traditional LBL methods which explicitly integrate over individual line shapes. In addition to quiescent atmospheric processes, this model calculates the auroral production and excitation of CO2, NO, and NO(+) in localized regions of the atmosphere. Illustrative comparisons of SHARC predictions to other models and to data from the CIRRIS, SPIRE, and FWI field experiments are presented.

THE EFFECTS OF ALTIMETER SAMPLING CHARACTERISTICS: SOME GEOSAT EXAMPLES Contract Report
Michael E. Parke and George Born 6 Apr. 1993 29 p
(Contract N00014-92-J-6004)
(AD-A275225; NRL-CR/7320-93-0002) Avail: CASI HC A03/MF A01

Altimetric satellites have characteristic sampling patterns in both space and time. This paper looks at the distortions of oceanographic and atmospheric signals as seen in Geosat altimeter data. Because of the pattern of ground tracks lain down by Geosat, measurements of oceanographic and atmospheric phenomena can be distorted spatially as well as temporally. As a result, phenomena measured by altimetric measurements can appear as propagating waves with both wavelength and wavenumber different from the original phenomena. These changes, if not understood, can result in misinterpretation of results from altimeter data. Also, in some parts of the world, distorted signals satisfy the dispersion relation of other oceanographic waves, or two phenomena can both have the same distorted dispersion relations. The use of multiple satellites to resolve these problems will be discussed in a follow-on paper.
